General information About Decision Support Systems

There are many DSSs must be developed for safety assessment for each situation and stage of flight of AC. Provision of informational support of DM by aircraft operator is possible in the conditions of data collection, processing and displaying of automation within a concept of perspective global CNS / ATM system (Communication, Navigation, Surveillance / Air Traffic Management), developed by ICAO (ICAO, 2007). The “system”, as defined for the purpose of safety assessment, will always be a sub-component of some larger system, such as ANS. For example, even if the assessment encompasses all services provided within an aerodrome, this can be considered a sub-component of a larger regional system, which in turn is a subcomponent of the global aviation system. A detailed description of the system should include (ICAO, 2013):

- the purpose of the system;
- how the system will be used;
- the system’s functions;
- the system’s boundaries and the external interfaces; and
- the environment in which the system will operate.

The safety impact of a potential loss or degradation of the system will be determined, in part, by the characteristics of the operational environment in which the system will be integrated. The description of the environment should, therefore, include any factors that could have a significant effect on safety. These factors will vary from one case to another. They could include, for example, traffic characteristics, airport infrastructure, and weather-related factors. Representation of the ANS in the form of a Socio-technical System makes possible to take into account the influence of the social, cultural environment of people who DM. Taking into account the influence on DM by H-O the professional factors (knowledge, habits, skills, experience) as well as the factors of non-professional nature (individual-psychological, psycho-physiological and socio-psychological) enables to predict the H-O’s actions and flight situation development with the aid of the informational, analytic and diagnostics complex for research operator behaviour in extreme situation and to develop DSS of ANS operators for each situation and each stage of flight (Kharchenko, Shmelova, & Sikirda, 2012, 2016).

DM problems and people, who make them, recently deserved more attention. This is due to the increasing dynamism of the environment, increasing interdependence of many decisions, the high rate of scientific and technological progress. Managers who make decisions are faced with difficult choices, with the need to consider the set of alternatives. To evaluate the options the knowledge of experts, sophisticated analytical calculations, scientific research, information technologies are used. Questions of decision support at all stages of the process (goal identification, development, and DM, organization, and implementation of control) are becoming more relevant. In fact, the problem consists of the automation of the creative work of the responsible employee’s groups of organizational management – managers of all levels and those who make decisions under actual conditions of their work. Three fundamental components of DSS architecture are the database (or knowledge base) – is an information structure that reflects the status and relationship of objects analyzed; the model base – is a set of mathematical, logical, linguistic and other models used for comparative analysis of multi-alternative decision; the user interface.

Computer support of technician's activity does not require a sophisticated methodological framework and is implemented within the framework of conventional information systems. As for executives and professionals, it is important to determine the nature and characteristics of preparing and decisions making based on the level of organizational management in order to create effective software of DSS as systems which use formal rules and object management model together with the database and personal experience to develop and validate variants of management decisions. Systems of this kind do not provide the information DM but participate in it.

The main methods of analytical modelling to support DM are:

- 1) *Factor analysis* ("cause-consequence") – is changing the values of some variables (factors) and their relationships (formulae) for the investigation of values changes of other, dependent, and variable (Data Mining).
- 2) *Optimization analysis* – is getting the best value of the objective function taking into account the restrictions imposed by the selection of variables (Decision Making).
- 3) *Correlation and regression analysis* – is determining the type of relations between the dependent variables and factors (Data Science).
- 4) *Trend analysis* – is predicting the dynamics of the control object by building trends – segments of numerical series (Data Mining).

Building a DSS should ensure implementation of its important properties:

- a) *The interactivity* of DSS means that the system responds to various types of action that one intends to influence the computational process, especially in interactive mode. Human and system exchange information at a rate that is comparable with the speed of human information processing.
- b) *The integrity* of DSS – is a complex of the system component for data management and communication with users during decision support.
- c) *The power* of DSS means the ability of a system to respond to the most significant question.
- d) *Availability* of DSS – is the ability to provide answers to the user requests in the right form and at the right time.
- e) *The flexibility* of DSS describes the possibility of adapting to needs and situations changing.
- f) *The reliability* of DSS means the ability of the system to perform the required functions for a given long period.
- g) *Robustness* of DSS – is the system's ability to recover in case of error situations, both external and internal origin. For example, there are mistakes of the input data or malfunctioning hardware in a robust system.

The DSSs for H-Os in working situational have been developed (Kharchenko, Shmelova, & Sikirda, 2012, 2016; Shmelova, Sikirda, Kasatkin 2019; Shmelova, Mirskova., & Krepak, 2017; Shmelova, Konovalova, 2017; Shmelova, Sikirda, & Belyaev, 2014). Authors presented examples of DSS for aviation operators in emergency such as DSS for ATC operator in the emergency situation and DSS of UAVs operator.

Decision Support Systems of Air Traffic Controller in Emergencies

Research has shown that the choice of the optimal variant of the flight completion in emergencies, which requires AC's forced landing, requires the operator to analyze the significant amount of diverse information. For a comprehensive account of the factors that affect the DM by an air traffic controller, has been built to adaptive DSS, which allows take into account the dynamic characteristics of the state of the control object (AC) and of the external environment (ATC zone). The main tasks of ATC DSS in flight emergencies are data collection about the state of the control object (AC), external environment (ATC zone) and the individual qualities of the person, who makes the decision; creation of action strategy in flight emergency (continue flight to the destination (alternate) aerodrome or perform a forced landing); modelling of DM by H-O in flight emergency; prediction of the flight situation development during DM by H-O in flight emergency; construction of the AC's field of approachability in case of necessity of forced landing; evaluating the effectiveness of alternative decisions in flight emergency and formation of recommendations for determination of the optimal variant of flight completion. The general concept of adaptive system for informational support of the DM by air traffic controller in emergency, which requires AC's forced landing, is presented in the form of a set of subsystems (Figure 3).

Figure 3. A conceptual model of an air traffic controller's DSS in flight emergencies, which is adaptive to changes in the state of the controlled object and of the external environment

Structure of ATC DSS in flight emergencies is shown in Figure 4. Functions of an air traffic controller's DSS in flight emergencies are expanded through information-analytical diagnostic complex for research of patterns of H-O's activity. By using complex, air traffic controller can predict the flight situation development, based on the operational monitoring of the pilot's emotional state and determining the effect of social environment on him.

The specialized program complex "Prompt" (Kharchenko, Shmelova, & Sikirda, 2012, 2016) has been created, in order to provide informational support to an air navigation system's operator. The program "Prompt" enables handling of two non-standard situations – an engine failure and fire on board of an

Figure 4. The structure of DSS of an air traffic controller in flight emergency, which requires AC's forced landing: AD – aerodromes, L – locality, LG – landing grounds; E – emotional state of H-O

aircraft (Shmelova, Kharchenko, Sikirda, & Gerasimenko, 2011). When the system receives a message about the unusual situation origination, the additional panel for providing the recommendations concerning the possibility of the flight continuation or necessity to execute a forced landing appears on the operator's monitor. When a type of situation – engine failure – is to be handled the number of the engines which have failed is to be input; when the type – fire – is to be handled, the condition of the aircraft is to be input and the proper advice appears on the monitor. When the recommendation concerning the necessity to accomplish a forced landing received, the field of approachability for the aircraft is built on the monitor, also values of the potential loss required for selection of a definite flight completion alternative as well as the coordinates of the potential landing sites (azimuth, range) are presented on the monitor. The program envisages the formation of the field of approachability for two extreme cases – the regime of planning and regime of an immediate descent (Figures 6). The program complex «Prompt» allows:

- to give the recommendations concerning the possibility of the further flight continuation or the necessity to accomplish a forced landing of the aircraft with the aid of the interface suitable for the user;
- to define the field of approachability of the aircraft in case when the necessity to make a forced landing arises;
- to form the evaluation of the alternative variants of the flight completion and define the optimum variant using the potential-loss minimization criterion.

Figure 5. The field of approachability and defined potential loss for a few variants of the flight completion in the event of the complete failure of the aircraft engines and in case of the fire on board the aircraft which has not been extinguished

Decision Support Systems of Unmanned Aerial Vehicle's Operator

Remotely Piloted Aircraft Systems (RPAS) are a new component of the aviation system, where the ICAO, States and the industry are working to understand, define and safe integration of RPAS into non-segregated airspace. These systems are based on cutting-edge developments in aerospace technologies, offering advancements that may open new and improved civil/commercial applications as well as improvements to the safety and efficiency of all civil aviation. Unmanned aircraft has several advantages, namely low operating cost, good concealment and flexibility, simplicity and availability of technology compared to manned aircraft and Unmanned Aerial Vehicles (UAV) can be used in cases where the usage of manned aircraft is impractical, expensive or risky (Austin, 2010).

The main advantage of using UAVs is tasks that involve risk to humans and efficiency in solving economic problems. Obviously, UAVs are effective in monitoring forest fires, search and rescue operations in the processing of agricultural crops, relay communications and the movement of goods. In this sense, the usage of UAVs is more appropriate: to relay communications at places where the antenna coverage cannot be set because of difficult terrain, in agriculture, aerial photography, moving cargo, for military purposes. Emergency situations may occur when flying both in manual and in the autonomous management. For operations carried out “manually” plays an important role in the human factor and a significant part of emergency arises due to the wrong actions of the operator. Today implementation of RPAS is necessary because they have transformed the idea of airpower in modern war times; they are smaller and less expensive than jet aircraft; don't put the pilots at risk when crash. Civil aviation has, to

this point, been based on the notion of a pilot operating the aircraft from within the aircraft itself and more often than without passengers on board. Removing the pilot from the aircraft raises important technical and operational issues, the extent of which is being actively studied by the aviation community. Most importantly, the introduction of remotely piloted aircraft into non-segregated airspace and at aerodromes should in no way increase safety risks to manned aircraft (ICAO, 2015).

Global operational air traffic management concept that reflects the ICAO vision of a single coherent and based on global modern mutually ANS systems should ensure collective consolidation to traffic management. Consolidation of information flows plays an important role in air traffic management. To make the right decision information that comes for air traffic controllers should be structured and consolidated information flows. In the implementation of this task the choice of database plays an important role. For rational aggregating requests and increase the processing speed NoSQL database has been proposed (Shmelova, 2016; Shmelova T., Sterenharz A., Burlaka O., 2019). Distributed DSS (DDSS) represents a complex system with complex interactions geographically distributed local DDSS operators of Remotely Piloted Aircraft (RPA). RPA is controlled by Remote Pilot Station (RPS) with the Command-and-Control (C2) line (Figure 6). Together with other components such as the starter equipment and equipment for the return, if it is used, RPA, RPS, and the C2 line constitute RPAS (ICAO, 2015).

Figure 6. The structure of distributed RPS Mission Control UAVs

The operational procedures of RPAS are determined by the aim of flight, rules of flights, areas of flights and functional data link from RPA. As the technologies develop RPA make their transition from strictly military usage to civil aviation and currently serve to fulfil many civil purposes. Actually it's very interesting to use DSSs for decision problems of pre-flight preparation, flight planning, DM in emergency situations. The main rule of effective realization of flight for piloted and unmanned aviation too is mandatory performance of pre-flight preparation including review and maintenance of the RPAS and RPS, obligatory checking of communication equipment and handling functions, configuration of RPS, downloading and checking of information that relates to flight planning procedure. Additionally, if it is necessary the clearance from ATC organizations should be received. One of the tasks that solve RPA pilot in the process of pre-flight preparation is a selection of alternate aerodromes/places for return procedure in the case of emergency situation that is caused by inappropriate meteorological conditions. Following documents regulate the selection of alternate aerodrome: flight manual, "Operation of decision making during IFR take-off and landing of aircraft of civil aviation of Ukraine" and other regulatory documents. The usage of RPA should be regulated by the same regulatory documents as for ordinary aircraft. RPA pilot should take into account the following factors:

- adequacy of fuel/energy reserve;
- distance to the alternate aerodrome/place;
- reliability of C2 lines for connection with RPA;
- possibility of communication with ATC units;
- meteorological conditions at the alternate aerodrome/place.

The multifunctional model of selection of alternate aerodrome/place of RPA has been proposed for economical effectiveness of flight realization of RPA which is used in remote system of decision making support of UAV's operator.

Illustrative Examples of Building Models for DSSs of UAV's Operator

To show the DSSs we use individual works of aviation students in education: Shulimov Oleh (*Example 1*), Fomin Olexandr (*Example 2*), (course "Basic of DM in ANS" in National Aviation University, Kyiv). In these examples the decision of selection tasks of alternate aerodrome/place in the case of emergency landing (difficult meteorological conditions, etc.) by method of DM in uncertainty is means of the criteria of DM in uncertainty: Wald, Laplace, Savage, Hurwicz. During approach of RPA of type N that flies along the route from the point A to point B , deterioration of meteorological conditions on the destination aerodrome appears. The task is to find optimal aerodrome/place of landing in the case of regular and irregular flight (first time realization).

Example 1: In a Case of Big UAV

Let's calculate the optimal landing aerodrome/place for RPA flying from Kharkiv to Kiev (Borispol) in a case of bad weather conditions: flight regular; for the first time; after two weeks. The matrix of possible results of DM that relates to choosing of optimal landing aerodrome/place in Table 1 has been obtained using MS EXCEL.

Table 1. The matrix of possible results of decision making that relates to choosing of landing aerodrome/ place for example 1

Alternative decisions		Factors that influence on decision making						Solutions			
A_i	A_{AAs}	Availability of fuel/energy onboard of RPA	Distance from RPA to $A_{Dest}, A_{Dep}, A_{AP}$	TTC of $A_{Dest}, A_{Dep}, A_{AP}$	Meteorological conditions at $A_{Dest}, A_{Dep}, A_{AP}$	Reliability of C2 lines for connection with RPA	Possibility of communication with ATC units	W	L	H	S
A_1	A_{ADest}	1	1	9	6	5	7	1	4,83	5	8
A_2	A_{ADep}	8	9	9	2	8	8	2	7,33	5,5	7
A_3	A_{AAP1}	5	6	3	3	6	3	3	4,33	4,5	3
A_4	A_{AAP2}	6	5	2	5	5	2	2	4,17	4	6
A_5	A_{AAP3}	5	7	7	4	4	1	1	4,7	4	6

Thus, according to the Wald and Savage (after calculation using the regret matrix) criteria the optimal solution is the alternative A3; according to the Laplace and Hurwitz criteria the optimal solution is the alternative A2.

Example 2: In a Case of Small UAV

As an example for our task we are going to consider RPA flight from Bila Tserkva aerodrome to Konotop with possible alternate destinations at Vasylkiv, Berezan' Nizhyn and Pryluky. For each aerodrome we have introduced risk parameters and corresponding coefficient which are going to serve as a basis for our investigation. The following parameters have been introduced: remoteness of the aerodromes, availability of fuel on-board, TTC of runways, reliability of C2 links, lightning systems and approach systems at aerodromes, meteorological conditions and navigational aids (Tables 2).

Table 2. The matrix of possible results of decision making that relates to choosing of landing aerodrome/ place for example 2

Alternative decisions		Factors that influence on decision making							Solutions			
A_i	A_{AAs}	Remoteness of the aerodromes	Availability of fuel onboard	TTC of runways	Reliability of C2 links	Lighting systems	Meteorological conditions	Navigational aids	W	L	H	S
A_1	Bila Tserkva	9	2	5	8	0	3	9	0	5,14	4,5	9
A_2	Konotop	3	5	7	9	2	4	9	2	5,57	4,5	7
A_3	Vasylkiv	2	8	8	9	2	4	10	2	6,14	6	8
A_4	Berezan'	7	1	8	7	1	7	7	1	5,43	5	7
A_5	Nizhyn	6	4	8	6	6	5	8	4	6,14	4,5	4
A_6	Pryluky	4	8	9	8	4	6	6	4	6,43	6,5	5

Thus, according to the Wald criterion, the optimal solutions are the alternatives A5 and A6; according to the Laplace and Hurwitz criteria the optimal solution is the alternative A6; according to the Savage (after calculation using the regret matrix) criterion the optimal solution is the alternative A5. For decision making using four criterion of estimation, such as Wald, Laplace, Hurwicz and Savage, the computer program “Classic Decision Criteria: Wald, Laplace, Hurwitz, Savage” (Shmelova, Shulimov, Chorna, & Kovtunets, 2015) has been designed.

FUTURE RESEARCH DIRECTIONS

Further research should be directed to the solution of the problem in prerequisites of emergency situations and preventing catastrophic situations too. Models of flight emergency development and of DM by ANS's H-O in-flight emergency will allow predicting the operator's actions with the aid of the informational-analytic and diagnostics complex for research of H-O behavior in extreme situations. It is necessary to develop collaborative DSSs of H-O of ANS (pilots, ATCs, flight dispatchers, UAV and SMS operators) for consolidation DM in an emergency. In future develop DSSs for operators in other areas such as chemical production, energy, military industry, medicine, etc.

On the next steps we are planning consider other collaboration DSSs, such as for hydraulic engineering, chemical and military industries, gas and oil pipelines, nuclear power plants and transport, etc. Developing of AI systems, Intelligent DSSs considering new concepts in aviation (PBA, CDM, SWIM, SMART, AI, etc.) for different operators and each stage, process, which are problems, with using modern information technologies Data Science, Big Data, Data Mining, DM, etc. It is necessary to analyze the all factors influencing on the DM of operators in these systems in order to predict the development of the technogenic catastrophe and prevent it with using Intelligent DSSs.

CONCLUSION

Conceptual models of air traffic controllers DSS in-flight emergencies and of flight dispatcher's DSS have been presented, program realization of systems has been shown. DSS of air traffic controller in-flight emergencies gives to the aviation operator possibility to quantify evaluation of alternatives of the flight situation development and to operatively choose an action strategy with minimal potential damage in the conditions of incomplete and uncertainty information. DSS of flight dispatcher provides the fast search of the information and support of the aviation operator during DM regarding the possibility of departure or regarding the optimal aerodrome in case of the forced landing of AC. It is reasonable to use an air traffic controllers DSS during the real Air Traffic Control in-flight emergencies, a flight dispatcher's DSS – in the automated system of pre-flight information preparation. The structure of the distributed DSS for RPA has been developed. For rational aggregating requests and increase the processing speed NoSQL database has been proposed. UAV (RPA) during the flight can be controlled by RPAS. RPA is controlled by RPS with C2 line. The computer program for the finding optimal landing aerodrome/place in an emergency situation on board of RPA that is caused by meteorological conditions has been designed.

KEY TERMS AND DEFINITIONS

AC: Aircraft.

ADS-B: Automatic dependent surveillance-broadcast.

Air Traffic Management (ATM): Is an aviation term encompassing all systems that assist aircraft to depart from an aerodrome, transit airspace, and land at a destination aerodrome, including Air Traffic Services (ATS), Airspace Management (ASM), and Air Traffic Flow and Capacity Management (ATFCM).

ANS: Air navigation system.

AS PIP: Automated system of pre-flight information preparation.

ASSIST: Acknowledge, separate, silence, inform, support, time.

ASSSIST: Acknowledge, separate, synergetic (coordinated, cooperation, consolidation), silence, inform, support, time.

ATC: Air traffic controller.

BVLOS: Beyond visual line of sight.

CNS/ATM: Communication, navigation, surveillance/air traffic management.

Collaborative Decision Making (CDM): Is a joint government/industry initiative aimed at improving air traffic flow management through increased information exchange among aviation community stakeholders.

Command and Control (C2): Denotes the set of organizational and technical attributes and processes by which an enterprise marshals and employs human, physical, and information resources to solve problems and accomplish missions.

Communication, Navigation, and Surveillance (CNS): Are the main functions that form the infrastructure for Air Traffic Management, and ensure that air traffic is safe and efficient.

Decision Support System (DSS): Is the interactive computer system intended to support different types of activity during the decision making including poorly-structured and unstructured problems.

Distributed Decision Support System (DDSS): Is a decision support system which supports distributed organizational decision making.

DM: Decision making.

Flight and Flow Information for a Collaborative Environment (FF-ICE): A product of the ICAO Global ATM Concept, that defines information requirements for flight planning, flow management and trajectory management and aims to be a cornerstone of the performance-based air navigation system.

Global Navigation Satellite Systems (GNSS): Is the common name of global satellite-based systems for navigation, positioning and time transfer. The most well-known system is the American system GPS (Global Positioning System) which got its operational status in 1994. Russia also has a similar system since the beginning of the 1990's called GLONASS (GLObal NAVigation Satellite System).

H-O: Human-operator.

ICAO: International Civil Aviation Organization.

IFR: Instrument flight rules.

NoSQL (Originally Referring to “Non-SQL” or “Non-Relational”) Database: Provides a mechanism for storage and retrieval of data that is modeled in means other than the tabular relations used in relational databases.

PANS: Procedures for air navigation services.

Performance-Based Approach (PBA): Is a decision-making method based on three principles: strong focus on desired/required results; informed decision making driven by those desired/required results and reliance on facts and data for decision making. The PBA is a way of organizing the performance management process.

Remotely Piloted Aircraft (RPA)/Remotely Piloted Aircraft System (RPAS)/Unmanned Aerial Vehicle (UAV)/Drone: Is a system that based on cutting-edge developments in aerospace technologies, offering advancements which are opening new and enhanced civil-commercial applications as well as improvements to the safety and efficiency of the entire civil aviation. The terms RPA or UAV are used to describe the aircraft itself, whereas the term RPAS is generally used to describe the entire operating equipment including the aircraft, the control station from where the aircraft is operated and the wireless data link.

RPS: Remote pilot station.

Safety Management System (SMS): Is the formal, top-down, organization-wide approach to managing safety risk and assuring the effectiveness of safety risk controls. It includes systematic procedures, practices, and policies for the management of safety risk.

SARPs: Standards and recommended practices.

SMART: Is a best practice framework for setting goals. A SMART goal should be specific, measurable, achievable, relevant and time-bound.

System-Wide Information Sharing and Management (SWIM): Is a Federal Aviation Administration advanced technology program designed to facilitate greater sharing of Air Traffic Management system information, such as airport operational status, weather information, flight data, status of special use airspace, and National Airspace System restrictions.

TTC: Tactical and technical characteristics.

VFR: Visual flight rules.

VLOS: Visual line of sight.

Classification and Recommendation With Data Streams

INTRODUCTION

Internet of Things (IoT), wireless sensor networks, social networks, crowdsourcing platforms and personal mobile devices are some examples of data stream sources. They continuously generate large volumes of real time data at variable rates, making traditional off-line processing obsolete. Data streams are sequences of timely ordered interactions between members of dynamic collections (Hopfgartner, Kille, Heintz, & Turrin, 2015). While continuous flows of information, they need real time incremental processing techniques to extract meaningful and timely information. With the exponential growth of data stream sources, data stream processing has become indispensable. Data stream algorithms have three main challenges: (i) present lower complexity to keep up with the data rate arrival and good scalability; (ii) display a manageable memory footprint; and (iii) adopt incremental techniques to build and maintain the model(s) updated. Specifically, the model updating process needs to prioritise information, *e.g.*, using novelty and relevance criteria, as well as to identify relevant data changes. Such challenges and problems require the design and development of new techniques to balance the computational complexity and the prediction performance. Data stream processing techniques have been extensively covered in several data mining books (Muthukrishnan, 2005), (Aggarwal, 2007), (Gama & Gaber, 2007), (Bifet, 2010), (Galić, 2016) (Garofalakis, Gehrke, & Rastogi, 2016). This article addresses data stream knowledge processing, ranging from classification to recommendation and evaluation, describing existing techniques, typical fields of application and identifying open challenges.

BACKGROUND

Data stream processing typically includes classification, recommendation and evaluation. Data stream classifiers work incrementally and attempt to classify events as they occur, *i.e.*, in near real time and not *a posteriori*. Micro-clusters (Aggarwal, Han, Wang, & Yu, 2004), decision trees (Rutkowski, Pietruczuk, Duda, & Jaworski, 2013), ensemble classifiers (Osojnik, Panov, & Dzeroski, 2017) and adaptive model

DOI: 10.4018/978-1-7998-3479-3.ch047

rules (Duarte, Gama, & Bifet, 2016) are well-known classification techniques which have been adapted to work with data streams. However, they suffer from concept drift, data outliers and missing data. Concept drifts can occur with time, *e.g.*, when interests change, and may arise from different situations, *e.g.*, changes in the properties of the data or inappropriate hyper-parameter tuning, are identifiable by alterations in the statistical properties of the data. In such cases, past observations become irrelevant to the current state and the algorithm needs to forget to improve its accuracy. Outliers correspond to data spatially distant from the trend of most of the observations. Outlier observations can be considered as hidden variables, inducing large statistical errors, and may indicate experimental error or unexpected variability in the measurement or noise. Missing values result from sensor malfunctioning or communication problems.

The data stream recommendation engines found in the literature rely on content-based or collaborative filters to generate personalised recommendations and popularity, recency, randomness or trending filters to make general recommendations. Popularity filters order items based on the item selection frequency / average rating; recency filters order the items based on the arrival date; the trend-based filters compute the frequency or rating trend of the items within a temporal sliding window; and random filters select randomly items to create a serendipity effect. To make personalised recommendations, content-based filters compute the similarity between the items previously selected and those not yet chosen by the active user, whereas collaborative filters learn user preferences and chose items appreciated by users with interests identical to the active user. With exception of collaborative filtering, the remaining approaches do not incorporate learning, which is essential to be efficient and reactive to the different user behaviours. Consequently, many of the simpler general filters tend to be used in combination with collaborative filtering. For this reason, we will focus our analysis on real time collaborative filters, which are extended versions of standard off-line model-based collaborative filters. They adopt incremental matrix factorisation (Peterek, 2007), (Takács, Pilászy, Németh, & Tikk, 2009), (Vinagre, Jorge, & Gama, 2014) to decompose the large user-item matrix into a product of smaller matrices and, then, apply other mathematical operations such as gradient based optimisation. By default, this technique has multiple challenges such as scalability, cold start, hyper-parameter optimisation and data relevance.

Finally, the evaluation of data stream algorithms, *i.e.*, the assessment of the quality of the predictions generated by a data stream classifier or recommendation engine, requires dedicated techniques such as sliding windows (Li, Maier, Tufte, Papadimos, & Tucker, 2005) (Ghanem, Hammad, Mokbel, Aref, & Elmagarmid, 2007), the prequential approach presented by (Gama, Sebastião, & Rodrigues, 2009) and the prequential Area Under the Curve (AUC) (Brzezinski, & Stefanowski, 2017).

LIMITATIONS OF EXISTING CLASSIFICATION AND RECOMMENDATION ALGORITHMS

The stream-based recommendation and classification algorithms present limitations in terms of data representation, model maintenance, performance and evaluation. Typically, researchers develop and tune their algorithms for off-line processing, using stored data sets and representing all entities. However, this approach is incompatible with on-line real-world data stream processing applications where events may arrive at various rates and tend to accumulate rapidly, generating large volumes of data. Furthermore, data streams, due to their inherent properties, are highly prone to data variability or concept drift, outliers and missing data. To timely process all events received, not only the incremental data processing has to remain simple, *i.e.*, have lower complexity, but parsimonious data representation techniques must be

adopted. In the latter case, it is necessary to prioritise data in terms of relevance. The goal is to minimise the memory footprint by discarding less relevant, outdated or noisy data.

The proper assessment of the stream-based algorithms raises other problems. With these algorithms, it is impossible to adopt standard off-line evaluation protocols, such as holdout or cross validation, since they are applied to the complete data set, which, in the case of a data stream, is by definition unknown. To overcome this problem, it's necessary to adopt incremental evaluation metrics or sliding windows to measure the performance of the algorithm considering the available data.

STREAM-BASED CLASSIFICATION, RECOMMENDATION AND EVALUATION

The focus of the article is to provide an overview of classification and recommendation with data streams. Specifically, it will cover existing techniques and report on problems, successes and open challenges.

In terms of online classifiers, the most used techniques are the micro clusters, decision trees, ensemble classifiers and adaptive model rules. However, the classification algorithms suffer from three types of problems: concept drift, which is a significant change on the statistical properties of the data, the occurrence of outliers, which introduces noise in the models and reduces the accuracy of the predictions, and the appearance of unlabelled data, which can be minimised by using imputation data.

The online recommendation algorithms typically use matrix factorisation techniques to build a preference model. These models can be extended using additional feature information to build more accurate models, *e.g.*, Anyosa, Vinagre & Jorge (2018) adopted a co-factorisation technique to add additional features to the model. However, these algorithms store all user preferences, including old user preferences which may no longer represent the current user tendencies. To minimise this drawback, relevance-based techniques, *e.g.*, forgetting, can be applied.

In terms of evaluation for online prediction algorithms, it was necessary to define new incremental performance measures to assess the performance of the prediction algorithms, *e.g.*, the predictive sequential evaluation protocol (Gama, Sebastião, & Rodrigues, 2009) and the usage of sliding windows to measure with more accuracy the learning behaviour of the data stream algorithms (Datar, Gionis, Indyk, & Motwani, 2002).

CLASSIFICATION

Data stream incremental classification techniques include: (i) micro-clusters, representing classes, which are built from clusters of data stream instances together with the corresponding summary of the statistics (Aggarwal, Han, Wang, & Yu, 2004); (ii) decision tree graph structures, holding in each node the available decisions and possible consequences (Rutkowski, Pietruczuk, Duda, & Jaworski, 2013); (iii) ensemble learning methods, which divide the problem into sub-problems, by applying individual classifiers specialized on each sub-problem, and combine the predictions of the individual classifiers to classify the incoming instances (Krawczyk, Minku, Gama, Stefanowski & Woźniak, 2017); and (iv) adaptive model rules, where data is split into several models or classes to build more accurate local models by creating new rules and discarding old rules (Duarte, Gama, & Bifet, 2016). On-line classifiers perform incremental adjustments to update the set of classes using different techniques: (i) gradient descent in the case of adaptive model rules (Duarte, Gama, & Bifet, 2016); (ii) recursive replacement of leaves by nodes, which verify the test conditions, in the case of decision trees (Hulten, Spencer,

& Domingos, 2001); (iii) random forest walks, an ensemble learning method which creates multiple alternative decision tree models to produce the best predictions together with resampling and adaptive operators to overcome concept drifts (Gomes et al., 2018); and (iv) ensemble learning with multi-target regression trees to classify multi-labels (Osojnik, Panov, & Dzeroski, 2017).

Several research efforts have been done to overcome concept drift, outliers and missing data affecting classification. Klinkenberg (2001) exploit the use of unlabelled data and sliding windows to discard irrelevant data. Hulten, Spencer, & Domingos (2001) adopt decision trees with a sampling window to improve the accuracy of the model without sacrificing the processing speed. Wang, Fan, Yu, & Han (2003) propose the use of ensemble classifiers to minimise the problem of the concept drift and outliers. Angiulli & Fassetti (2007) detected outliers based on the distance between an object and its neighbours, using the Euclidian distance. Pokrajac, Lazarevic & Latecki (2007) describe an outlier detection scheme based on the distance between observations and their density. Jaworski, Duda, Rutkowski, Najgebauer, & Pawlak (2018) suggest the adoption of Parzen kernels – a regression technique – extended with sliding windows and forgetting factors to detect concept drifting. To surpass the missing data problem, Saar-Tsechansky, & Provost (2007) suggest the use of imputation, omission or analysis. Specifically, Montiel, Read, Bifet, & Abdesslem (2018) automatically impute missing data, regardless of the characteristics of the data set, by means of a cascade imputation technique.

Examples of applications of this type of algorithms are sensor monitoring, financial and marketing predictive models.

RECOMMENDATION

Recommendation algorithms for data streams are incremental. There are several approaches in the literature, ranging from matrix factorization (Koren, Bell, & Volinsky, 2009), matrix factorization with gradient descent (Burgess et al., 2005) to ensemble methods (Vinagre, Jorge & Gama, 2018) and co-factorisation (Anyosa, Vinagre, & Jorge, 2018). Every time a new user event arrives, the model is updated, and new personalised recommendations are provided. Matrix factorisation scalability is an issue due to the continuous arrival of new users and items, producing huge sparse matrices, which require large volumes of memory. To overcome this scalability problem of collaborative filters, it is possible to partition the data or migrate to the cloud, *e.g.*, using a distributed algorithm like Apache Spark together with Hadoop (Meng et al., 2016).

The representation of new users and items – cold-start – is particularly hard to overcome in the case of data streams. A typical approach is to add new lines or columns to the matrix model and initialise the new latent vectors, *e.g.*, with random values centred around a predefined value (Matuszyk, Vinagre, Spiliopoulou, Jorge, & Gama, 2017) or the average value of similar items.

Standard hyper-parameter optimisation is normally performed off-line, involving multiple training and validation stages, and include grid search, random search, stochastic gradient or Bayesian optimisers. The only exception are the works of Pfaffe, Tillmann, Walter, & Tichy (2017) and Veloso, Gama, & Malheiro (2018), where the Nelder-Mead optimisation is adopted to tune model hyper-parameters on-line.

Another important aspect when processing data streams is the ability to recognise the relevance of the data, *e.g.*, to distinguish between old and new information. However, since matrix factorisation algorithms build models based on the all observations received so far (Vinagre, Jorge & Gama, 2014), they are unable to discriminate between old and recent data. Matuszyk et al. (2017) proposed the adoption of factor fading together with first in, first out (FIFO) queues and (Koren, 2010) introduced the usage

of time-dependent bias. Anyosa, Vinagre & Jorge (2018) explore co-factorisation algorithms to build a more accurate models, taking into consideration additional features. Wang et al. (2018) propose a probability-based approach by combining SGD with pairwise probabilistic matrix factorisation models.

More recently, there is a trend to adopt ensemble methods for data stream recommendation data to outperform single models. Vinagre, Jorge, & Gama (2018) apply ensemble methods to reduce the variance of data and Matuszyk, & Spiliopoulou (2018) rely on specialised ensemble semi-supervised co-trainers to alleviate the problem of data sparsity.

These algorithms are extensively used within e-commerce, video and music streaming platforms.

EVALUATION

The typical data stream evaluation metrics determine the error, *e.g.*, the incremental Root Mean Square Error (RMSE) (Takács, Pilászy, Németh, & Tikk, 2009), and the accuracy, *e.g.*, the incremental Recall@ N (Cremonesi, Koren, & Turrin, 2010). The incremental RMSE calculates the RMSE after each new viewer rating event (Takács, Pilászy, Németh, & Tikk, 2009). The incremental Recall@ N , for each new event, selects 1000 items not yet rated by the active user, adds the newly rated item and, then, makes predictions for this subset of 1001 items. Finally, it sorts the 1001 predictions by descending order and, if the newly rated item belongs to the list of the top N viewer predictions, counts a hit (Cremonesi, Koren, & Turrin, 2010).

Regarding the evaluation of data streams, there are three main approaches: (i) sliding windows to measure the performance metrics in given timespan (Datar, Gionis, Indyk, & Motwani, 2002); (ii) predictive sequential evaluation to calculate the performance metrics incrementally (Gama, Sebastião, & Rodrigues, 2009), *i.e.*, instance by instance; and (iii) the prequential Area Under the Curve (AUC) (Brzezinski, & Stefanowski, 2017). Typically, sliding windows are data windows with predefined size and slide rate where the evaluation metrics are calculated. The predictive sequential evaluation – prequential evaluation – assesses the predictions generated for each new event before updating the model, using the incremental RMSE and Recall@ N . The prequential AUC, suggested by Brzezinski, & Stefanowski (2017), uses a sorted tree and a forgetting sliding window to compute the AUC as originally proposed by (Hanley & McNeil, 1982). Depending on the data rate, the evaluation process may still take too long, leading to the adoption sample-based evaluation methods.

According to (Krawczyk, Minku, Gama, Stefanowski, & Woźniak, 2017), apart from the predictive accuracy or error, additional performance metrics should be monitored and taken into account during properly executed evaluation of streaming algorithms: memory consumption, update time and decision time. The memory footprint of stream algorithms needs to be monitored to know beforehand the type and quantity of resources required. The model update time provides an indication of the complexity and efficiency of the adopted algorithm (the update time should be lower than the arrival interval between instances). The decision time corresponds to the time interval required by the model to make a decision regarding new events. This is especially crucial for algorithms that cannot update and make predictions regarding new instances at the same time.

Last, but not least, the evaluation of data stream algorithms tends to be non-reproducible due to the endless nature and data volume. To avoid this problem, researchers create partial data sets from real data streams or reuse existing data sets with timestamped data for benchmarking data stream algorithms.

FUTURE RESEARCH DIRECTIONS

Although data stream processing is a highly active research domain, there are several issues which require further exploration. In terms of classification, there is the need to design innovative algorithms for the early detection of data anomalies (outliers, concept drifts and missing data) and optimise the data partition sizes.

Regarding recommendation, it is necessary to develop different algorithms and new approaches because most of the contributions for data streams are based on matrix factorisation. The problem of hyper-parameter optimisation, which is common to classification and recommendation, has a large impact on the performance of the algorithms and, thus, needs to be further addressed. Currently, researchers are giving the initial steps on progressive automation of machine learning (AutoML) in order to substitute machine learning experts, including automated hyper-parameter tuning. In terms of future developments, there are two critical points requiring further research: the detection user preference evolution and the scalability of the on-line algorithms. While the first will lead to the design of more robust and efficient forgetting techniques, the latter will rely on new model compressing techniques to reduce the data dimension and on the optimisation of the parallel implementation of recommendation engines.

Finally, classification and recommendation algorithms need to embrace further the lack of information problem, including both the non-arrival and the late arrival of events, as well as the design continuous self-tuning incremental models, *e.g.*, hyper-parameter meta-learners.

In terms of evaluation of the recommendation with data streams, it is necessary develop evaluation mechanisms not only focussed on performance parameters like predictive and accuracy metrics, but also on the algorithm runtime and computational resources used, to find the necessary commitment between functional and non-functional parameters. Additionally, it is important to evaluate the learning behaviour of the algorithms.

CONCLUSION

The presented techniques are intended for scenarios where the information is dynamic, continuous and unknown. Their main goal is to build and maintain updated models, capable of the capturing the relevant patterns as they occur, to make accurate predictions. The foundations of data streams algorithms are incremental processing, to reduce the computational requirements required to process large quantities of data, and relevance model updating, adjust the data stream model to the current user trends. In terms of research, this topic covers a large set of real problems, including sensor networks, crowdsourced data and web analysis. The numerous fields of application illustrate the relevance of stream-based knowledge techniques, ranging from industrial sensor networks to financial and e-commerce platforms.

Recently, there are several alternatives proposed by researchers for three core topics of data stream processing: classification, recommendation and evaluation. The tendency is to create more advance and accurate algorithms with the help of increased computational resources, *e.g.*, cloud computing. Data anomalies, *e.g.*, concept drifts, outliers and missing data, contribute to the decrease of the overall performance of the algorithms, suggesting the need to design novel and more advanced techniques, supported by automated learning, to dynamically adapt to the behaviour of the incoming data. Specifically, we anticipate that computer processing power, parsimonious data representation and innovative self-tuning algorithms will be essential for the near future of data stream processing. Finally, the evalu-

ation of stream processing techniques requires further exploration since the available techniques are extensions of off-line evaluation.

KEY TERMS AND DEFINITIONS

Automatic Machine Learning: Is the automation of complex data mining tasks for example hyper-parameter optimization.

Classification: Is the task that assigns items to a set of classes.

Concept Drift: Represents the change over time of the distribution of a target variable.

Data Mining: Is the process that identifies and collects patterns in data sets.

Data Streams: is a continuous flow of data to be processed by an algorithm.

Evaluation: Is the task of judge and assessing if the predictions generated by a classification or recommendation algorithm scores on the target value.

Hyper-Parameter: It is used to describe the parameters that an algorithm/model requires to work.

Recommendation: Is an algorithm that tries to identify patterns and make predictions based on the past user behaviour.

N-Tuple Algebra as a Generalized Theory of Relations

INTRODUCTION

In information technologies, analysis of heterogeneous information often necessitates unification of presentation forms and processing procedures for such data. One of the promising ways to solve this problem is the search for a universal structure, which allows reducing various data and knowledge models to a single mathematical model with unified analysis methods. One of such universal structures is the relation, which is mainly associated with databases modeled by means of relational algebra (Codd, 1971). However, relations are used not only in databases. They can model as different, at first glance, mathematical objects as graphs, networks, artificial intelligence structures, predicates, logical formulas, etc. Representation and analysis of such structures and models requires for more expressive means and methods than relational algebra provides.

So, with a view to developing a general theory of relations, the authors propose n -tuple algebra (NTA) developed as a theoretical generalization of structures and methods applicable in intelligence systems. NTA allows for formalizing a wide set of logical problems (deductive, abductive and modified reasoning, modeling uncertainties and so on). Besides, this paper considers matters of metrization and clustering for NTA objects with ordered domains of attributes.

BACKGROUND

Nowadays, intelligence systems include two types of dissimilar objects, namely databases (DBs) and knowledge bases (KBs). Their structures are fundamentally different, since their construction is based on different theoretical approaches. Modern data structures (numbers, vector graphs, networks, texts, etc.) exploit algebraic techniques (Wirth, 1976). As for KBs, their basic models (predicates, frames, semantic networks, rules) are built on the basis of declarative approaches (Russel & Norvig, 2003). This discrepancy results in significant differences of programming systems for DBs and KBs and, accordingly, in large expenditures of time and money to couple DBs and KBs in one software system. Conventional cases to attempt this integration are mostly accomplished within declarative approaches. An example is the deductive database model (Ullman, 1989; Ceri, Gotlob, & Tanca, 1990), which is based on a modified Prolog programming language intended for computer implementation of the declarative approach.

Conversely, some shortcomings inhere in this approach. One of the main problems is that when using a declarative approach, many tasks of logical analysis need to be reduced to satisfiability checks for a

DOI: 10.4018/978-1-7998-3479-3.ch048

certain logical formula where only two possible answers (“yes” or “no”) are possible. Such a reduction is not simple. Moreover, it is unrealizable in cases when one needs to not only receive a binary answer but also to estimate the value of some parameters in the formal system or to assess the structure and/or number of objects that satisfy the given conditions.

When modeling and analyzing modifiable reasoning (i.e., reasoning with hypotheses and abductive conclusions), many researchers recommend using non-classical logic (default logic, non-monotonic logic, etc.) (Russel & Norvig, 2003), since it is believed that classical logic is ill-suited for solving such problems. However, in many cases, interpretations of non-classical logics are either missing or not corresponding to the semantics of the objects being modeled. There are reasons to assume that the difficulties of modeling modifiable reasoning within the framework of classical logic are not due to the shortcomings of this logic, but to the specifics of the declarative approach.

Algebraic approach to logical modeling can be originated from Aristotle’s syllogistics and Boole’s logical matrices, in more recent times only Arkady Zakrevskij (for instance, see (Zakrevskij & Gavrilov, 1969)) investigated set-theoretical approach to logic and proposed a programming language LYaPAS (Logical Language for Representation of Synthesis Algorithms) oriented toward programming of synthesis algorithms for finite-state and discrete devices. However, this language does not provide any means for logical inference.

To overcome the mentioned and other problems, the mathematical model of relational algebra was generalized by the authors to a more universal system for processing n -ary relations called n -tuple algebra (Kulik, 1995, 2007; Kulik & Fridman, 2017). Its main features and provided opportunities are introduced below.

N-TUPLE ALGEBRA: BASICS AND FEATURES

The algebraic approach to modeling systems stipulates that some homogeneous objects (numbers, vectors, matrices, etc.) are used as basic structures. In n -tuple algebra (NTA), such objects are relations, which can be expressed as four types of structures called **NTA objects**. Every NTA object is immersed into a certain space of variables called **attributes**. Each attribute is represented by a set of possible values called **domains**, and the spaces themselves are defined as Cartesian products of these domains.

Names of NTA objects contain an identifier followed by a sequence of attributes names in square brackets; these attributes determine the **relation diagram** in which the NTA object is defined. For example, $R[XYZ]$ denotes an NTA object defined within the space of attributes $X \times Y \times Z$ that is $R[XYZ] \in X \times Y \times Z$.

From the mathematical point of view, NTA is an **algebraic system** $A = \langle A, O, R \rangle$, where the **carrier** A is an arbitrary totality of relations expressed as NTA objects; O is a set of **operations** comprising **algebra of sets’ operations** (union, intersection, complement) and **operations on attributes** (see below); R is a set of verified **relations** between NTA objects, namely equality and inclusion. This algebraic system is proved to be complete (i.e. all operations and checks of relations are feasible for any totalities of NTA objects).

NTA objects defined on the same relation diagram are called **homotypic** ones. NTA objects contain n -tuples of sets and provide a concise representation of n -ary relations. In NTA, **elementary n -tuples** correspond to n -tuples of elements in ordinary relations. For instance, the record $T[XYZ] = (a, b, c)$ means that T is an elementary n -tuple where $a \in X, b \in Y, c \in Z$.

NTA objects look like matrices having subsets of corresponding attributes (**components**) rather than elements as their cells. The totality of NTA components includes two **dummy components**. They are: the **complete component** “*” that equals to the whole domain (i.e. the range of values) of the corresponding attribute in the relation diagram and the **empty component** “ $\emptyset$ ” that equals to the empty set and models the complement of the component “*”.

NTA admits four types of NTA objects, namely C -n-tuples and C -systems, D -n-tuples and D -systems.

A **C -n-tuple** is an n -tuple of components defined in a certain relation diagram, denoted within square brackets and interpreted as the set of elementary n -tuples contained in the Cartesian product of its components. For example, the right part of the formula $R[XYZ] = [A * C]$ expresses a C -n-tuple that can be transformed into an ordinary n -ary relation by calculating the Cartesian product $A \times * \times C$ where $A \subseteq X$, $* = Y$ is a complete component placed to the position of the attribute Y , and $C \subseteq Z$.

A **C -system** is a set of homotypic C -n-tuples that are denoted as a matrix in square brackets. As an example, the C -system $Q[XYZ] = \begin{bmatrix} A_1 & B_1 & * \\ * & B_2 & C_2 \end{bmatrix}$ can be reduced to a set of elementary n -tuples calculated as $Q[XYZ] = (A_1 \times B_1 \times Z) \cup (X \times B_2 \times C_2)$.

A **D -n-tuple** expresses a structure that can be interpreted, in particular, as a complement of a certain C -n-tuple. Suppose, the C -n-tuple $R[XYZ] = [A B C]$ is given. Its complement equals to the difference of the C -n-tuples $[X Y Z] \setminus [A B C] = (X \times Y \times Z) \setminus (A \times B \times C)$. The formula of difference for two Cartesian products is well known, for the given example it equals:

$$(X \times Y \times Z) \setminus (A \times B \times C) = ((X \setminus A) \times Y \times Z) \cup (X \times (Y \setminus B) \times Z) \cup (X \times Y \times (Z \setminus C)).$$

In NTA terms, the right part of this formula can be denoted as the C -system

$$\bar{R}[XYZ] = \begin{bmatrix} \bar{A} & * & * \\ * & \bar{B} & * \\ * & * & \bar{C} \end{bmatrix}$$

where $\bar{A}$, $\bar{B}$, $\bar{C}$ mean complements of the components A , B , C to the domains of corresponding attributes.

The square C -systems like $\bar{R}[XYZ]$ where all nondiagonal cells contain complete components are called **diagonal C -systems**. Without any loss of information, they can be written as an n -tuple of the diagonal components. To distinguish them from C -n-tuples in NTA, we use reversed square brackets instead of regular ones. So, for the given example $\bar{R}[XYZ] =] \bar{A} \bar{B} \bar{C} [$.

A **D -system** is a structure that consists of a set of homotypic D -n-tuples and equals to their intersection. The list of D -n-tuples in a D -system is framed with reversed square brackets.

In order to better understand relationships between different types of NTA objects, consider an example. Let the attribute space $[XYZ]$ be given, where $X = \{a, b, c, d\}$, $Y = \{f, g, h\}$, $Z = \{a, b, c\}$. There is a C -system defined in this space:

$$F[XYZ] = \begin{bmatrix} \{a, b, d\} & \{f, h\} & \{b\} \\ \{b, c\} & * & \{a, c\} \end{bmatrix}.$$

Then the complement of $F[XYZ]$ is the D -system

$$\bar{F}[XYZ] = \begin{bmatrix} X \setminus \{a, b, d\} & Y \setminus \{f, h\} & Z \setminus \{b\} \\ X \setminus \{b, c\} & Y * & Z \setminus \{a, c\} \end{bmatrix} = \begin{bmatrix} \{c\} & \{g\} & \{a, c\} \\ \{a, d\} & \emptyset & \{b\} \end{bmatrix}.$$

In turn, according to the duality law in algebra of sets, since the C -system $F[XYZ]$ is the union of the C - n -tuples contained in it, the D -system $\bar{F}[XYZ]$ can be represented as the intersection of the D - n -tuples it contains:

$$\bar{F}[XYZ] =]\{c\} \{g\} \{a, c\}[\cap]\{a, d\} \emptyset \{b\}[.$$

NTA laws are based on the laws of algebra of sets and properties of the Cartesian product. Let us introduce main NTA relationships.

Suppose two homotypic C - n -tuples $P = [P_1 P_2 \dots P_n]$ and $Q = [Q_1 Q_2 \dots Q_n]$ be given. Then:

- 1) $P \subseteq Q$, if and only if $P_i \subseteq Q_i$ for all $i = 1, 2, \dots, n$;
- 2) $P \cap Q = [P_1 \cap Q_1 P_2 \cap Q_2 \dots P_n \cap Q_n]$. Moreover, if for any i $P_i \cap Q_i = \emptyset$, then $P \cap Q = \emptyset$;
- 3) $P \cup Q = \begin{bmatrix} P_1 & P_2 & \dots & P_n \\ Q_1 & Q_2 & \dots & Q_n \end{bmatrix} \subseteq [P_1 \cup Q_1 P_2 \cup Q_2 \dots P_n \cup Q_n]$;
- 4) equality $P \cup Q = [P_1 \cup Q_1 P_2 \cup Q_2 \dots P_n \cup Q_n]$ is possible in two cases only:
 - (i) $P \subseteq Q$ or $Q \subseteq P$;
 - (ii) $P_i = Q_i$ for all corresponding pairs of components except one pair;
- 5) $\bar{P} =]\bar{P}_1 \bar{P}_2 \dots \bar{P}_n[.$

Numerous examples of representing different data and knowledge structures as NTA objects are given in the references to our publications listed below. Due to size limits of this paper, we give only one example of how to apply NTA structures for logical analysis. This example uses variables that contain more than two values, which makes it possible to analyze the logic models that go beyond the propositional calculus. Suppose we want to find the object, which is in one of three rooms. At the same time, you may not enter one of the rooms (there is a danger), and one of the rooms is empty. There are two following clues.

- 1) The first room is not dangerous, the second is not empty;
- 2) The third room is not dangerous, the second is not empty.

We also know that one of the clues is true, the other one is false.

Let us denote A the statement “the room contains the desired object”, B – “the room is empty” and C – “the room is dangerous”. Attributes names will be equal to the names of the rooms R_1, R_2, R_3 . Each of these rooms corresponds to one of situations from the permitted situations set $\{A, B, C\}$.

The given conditions can be expressed by C - n -tuples as follows.

- 1) $T_1[R_1 R_2 R_3] = [\{A, B\} \{A, C\} *];$
- 2) $T_2[R_1 R_2 R_3] = [* \{A, C\} \{A, B\}].$

To solve the problem, it is necessary to consider two possible cases: 1) The first clue is true, and the second is false; 2) The first clue is false, and the second is true.

Let us consider the first case. If T_2 is false, its negation $\bar{T}_2 =] \emptyset \{B\} \{C}[$ is true. To find a solution, one needs to find the intersection of the true conditions:

$$T_1 \cap \bar{T}_2 =]\{A, B\} \{A, C\} *] \cap] \emptyset \{B\} \{C}[=]\{A, B\} \{A, C\} *] \cap \begin{bmatrix} * & \{B\} & * \\ * & * & \{C\} \end{bmatrix} =]\{A, B\} \{A, C\} \{C}[.$$

The resulting C -n-tuple contains 4 possible placement options (one can find this by calculating the Cartesian product of $\{A, B\} \times \{A, C\} \times \{C\}$). However, according to the conditions of the problem, the correct placement must have different situations in different rooms, i.e. the only placement (B, A, C) is correct. It means that the desired object is located in the second room. Similar results can be obtained when testing the second case.

The above listed relationships provide proving all the rest NTA laws, which assisted in composing algorithms of NTA operations and checks of equality and inclusion for any homotypic NTA objects.

To implement NTA operations and checks for any (possibly non-homotypic) NTA objects, it is necessary to define generalized operations and relations based on some operations upon attributes.

NTA: GENERALIZED OPERATIONS AND OPERATIONS UPON ATTRIBUTES

Let us introduce operations on attributes first.

Renaming of attributes is used when it is necessary to substitute variables, particularly, in algorithms for calculating transitive closure of a graph.

Transposition of attributes is an operation that swaps columns in an NTA object's matrix and respectively changes the order of attributes in the relation diagram.

If an NTA object contains two columns, the permutation of attributes without permutation of columns (or, equivalently, permutation of columns without permutation of attributes) corresponds to the operation of **reversing relations**.

Elimination of an attribute ($-Attr$) is done in the following way: a column is removed from an NTA object, and the corresponding attribute is removed from the relation diagram.

Addition of a dummy attribute ($+Attr$) is done when the added attribute is not yet present in the relation diagram of an NTA object. This operation adds the name of a new attribute into the relation diagram and simultaneously adds a new column with dummy components into the corresponding place; dummy components “*” are added into C -n-tuples and C -systems, and dummy components “ $\emptyset$ ” are added into D -n-tuples and D -systems.

By defining the operation $+Attr$, we have eliminated the restriction in the theory of relations stating that algebra-of-sets laws are only applicable to the relations defined upon the same Cartesian product.

The operation $+Attr$ is often used to reduce some different-type NTA objects to the same relation diagram by adding the missed attributes. Then one can perform all necessary operations and checks by means of standard NTA algorithms.

Considering this, we have introduced **generalized operations** ($\cap_G, \cup_G$). They differ from corresponding operations of algebra of sets by the only feature: NTA objects are reduced to the same relation diagram

before execution of these operations, which are semantically equal to logical connectives: disjunction and conjunction correspondingly. **Generalized relations** ($\in_G$ and $=_G$) are defined similarly.

Algebra of n -ary relations with the mentioned generalized operations and relations is proved to be isomorphic to the conventional algebra of sets.

NTA: CORRESPONDENCE WITH PROPOSITIONAL AND PREDICATE CALCULI

A C - n -tuple corresponds to the **conjunction** of unary predicates with different variables. For example, in predicate calculus, the C - n -tuple $P[XYZ] = [P_1 P_2 P_3]$ where $P_1 \subseteq X$; $P_2 \subseteq Y$; $P_3 \subseteq Z$ models the logical formula $H = P_1(x) \wedge P_2(y) \wedge P_3(z)$ where X , Y and Z are ranges of values for the variables x , y and z .

A D - n -tuple corresponds to the **disjunction** of unary predicates with different variables. For instance, the D - n -tuple $Q[XYZ] =]Q_1 Q_2 Q_3[$ corresponds to the logical formula

$$F_2(x, y, z) = Q_1(x) \vee Q_2(y) \vee Q_3(z).$$

C -systems are convenient for representing **disjunctive normal forms** (DNFs) of unary predicates, and D -systems model **conjunctive normal forms** (CNFs) of unary predicates.

An elementary n -tuple that is a part of a non-empty NTA object corresponds to a **satisfying substitution** in a logical formula.

An empty NTA object corresponds to an **identically false formula**.

An NTA object $P[XY...Z]$ that equals to $X \times Y \times \dots \times Z$ corresponds to a **valid formula**, or a **tautology**.

A non-empty NTA object models a **satisfiable formula**.

Now let us consider quantifiers in NTA.

Adding a dummy attribute to a C - n -tuple or a C -system corresponds to the **rule of generalization** in predicate calculus. For example, if an NTA object

$$G[XZ] = \begin{bmatrix} \{a, c\} & * \\ \{a, c, d\} & \{b, c\} \end{bmatrix}$$

corresponds to a formula $F(x, z)$ of this calculus, by adding a dummy attribute Y into this NTA object we get an NTA object

$$G_1[XYZ] = +Y(G[XZ]) = \begin{bmatrix} \{a, c\} & * & * \\ \{a, c, d\} & * & \{b, c\} \end{bmatrix}$$

which models the formula $\forall y F(x, z)$.

Elimination of an attribute from a C -system (D -system) is proved to be equivalent to the universal (existential) quantification on this attribute. Thus, if an NTA object $R[XYZ]$ models a formula $F(x, y, z)$, then $-Y(R[XYZ])$ corresponds to $\exists y F(x, y, z)$, if $R[XYZ]$ is a C -system, and to $\forall y F(x, y, z)$, if $R[XYZ]$ is a D -system.

To obtain NTA representations for formulas of propositional calculus containing logical variables $x_1, x_2, \dots, x_n$, it is enough to assign every variable x_i with the attribute $X_i = \{0, 1\}$. Then the dummy com-

ponent * corresponds to the set $\{0, 1\}$, literal x_i corresponds to $\{1\}$, and its negation $\neg x_i$ corresponds to $\{0\}$. For example, the formula

$$F(x, y, z) = (x \vee \neg z) \wedge (\neg y \vee z) \text{ corresponds to the } D\text{-system } R[XYZ] = \begin{bmatrix} \{1\} & \emptyset & \{0\} \\ \emptyset & \{1\} & \{0\} \end{bmatrix}.$$

The negation of this formula

$$\neg F(x, y, z) = (\neg x \wedge z) \vee (y \wedge \neg z) \text{ is modeled by the } C\text{-system } \bar{R}[XYZ] = \begin{bmatrix} \{0\} & * & \{1\} \\ * & \{0\} & \{1\} \end{bmatrix}.$$

It is easy to see that relations between C -objects (C - n -tuples and C -systems) and D -objects (D - n -tuples and D -systems) are in accordance with de Morgan's **laws of duality**. Due to this fact, they are called **alternative classes**.

All NTA objects model scopes of truth for their corresponding logical formulas. In NTA, attribute domains can contain arbitrary sets of values that are not necessarily equal to each other. Thus, NTA structures model formulas of **many-sorted predicate calculus**.

This paper does not consider matters of complexity in detail; they are described in (Kulik, 1995). Here, we would like to note that NTA structures can be polynomially reduced to logical ones; hence *the computational complexity of algorithms on NTA structures fully corresponds to the computational complexity of algorithms solving problems on logical structures*. A significant number of such problems arising during logical analysis by means of deduction procedures (for instance, the satisfiability problem for a CNF) are NP-complete problems with regard to their computational complexity. However, the matrix properties of NTA objects allowed us to find some special cases that are solvable in polynomial time only (Kulik, 1995). Moreover, such structure is good to reduce computational complexity of NTA operations by their effective parallelization (Kulik & Fridman, 2014).

LOGICAL INFERENCE IN NTA

Theoretical principles of NTA provide solving the following problems of deductive analysis.

- 1) *Problem of correctness check for an alleged consequence B from the given premises A_i .*
- 2) *Problem of deriving possible consequences from the given premises A_i considering certain semantical constraints, for instance, presence of given variables or their combinations in a consequence, deriving a consequence with the minimal number of significant variables, etc.*

Unlike other logical systems that solve such problems by using inference rules with hardly optimized order of their implementation, NTA solves these problems by means of certain standard algorithms. To do so, we transform classical logic' formulas, which express premises and consequences, into NTA objects and subject these objects to generalized operations and checks of equality ($=_G$) or inclusion ($\in_G$). The transition to the algebraic representation becomes clearer, if you consider that NTA objects model scopes of truth for logical formulas. Then the correctness proof for an alleged consequence B from the premises A_i requires for calculating generalized intersections and checking the following generalized inclusion:

$$(A_1 \cap_G \dots \cap_G A_n) \subseteq_G B \quad (1)$$

Considering (1), the problem to derive possible consequences $\{B_j\}$ from the given premises A_i can be solved in NTA by using the relation that must be true for every B_j : $A \subseteq B_j$, where $A = A_1 \cap_G \dots \cap_G A_n$. Thus, any correct consequence from premises A_i can be modeled by an NTA object representing a superset of A . To find such objects, NTA proposes several techniques. One of them is **calculating projections of an NTA object**. This operation is simple if A is a C -system. Then the projection can be found by operation $-Attr$. It is easy to prove that any projection of an NTA object models its superset. This technique allows checking the possibility to obtain consequences containing certain variables.

The relationship (1) allowed for an NTA definition of the **minimal consequence** from axioms $A_1, A_2, \dots, A_n$ that equals to the NTA object $A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$. This consequence is the minimal one as it is proved to satisfy the two following statements:

- 1) any strict subset of A is not derivable from the axioms $A_1, A_2, \dots, A_n$;
- 2) if S is an arbitrary NTA object from a proper universe, the NTA object $A \cup S$ is derivable from the axioms $A_1, A_2, \dots, A_n$.

In some kinds of reasoning models, a consequence B is considered a suitable solution of an inference task if this consequence contains fewer variables than the minimal consequence A (such a consequence can be found by using the above-introduced technique. This decrease in number of variables in the formula $B = A \cup S$ results from transformation of some variables in the formula A into dummy ones after adding S to it.

NTA: MODELS OF PLAUSIBLE REASONING

Some difficulties in applying propositional and predicate calculi to analysis of plausible reasoning arose from the fact that mathematical logic recognizes inconsistency of a reasoning system (a theory) if and only if both a corollary and its negation follow from the same premises. Conversely, commonsense reasoning recognize inference of contrary corollaries (for instance, both statements “All A are B ” and “No A are B ”) as a definite criterion of inconsistency for a knowledge system though they are not formally contradictory.

In order to eliminate this and other discrepancies between formal logic and natural deduction, we propose a concept of “**collision**” in our logical analysis system (Kulik, 1995).

Unlike a logical contradiction, collisions can have opposite interpretations in different cases. For example, within one system the equality $R = \emptyset$ means the absence of an object that is necessary for existence of the system, and in another system (where the object R is not necessary) this equality specifies a status of this object. The first case requires for changing the premises while the second case provides a new useful knowledge.

Collisions mostly occur during defeasible reasoning when new knowledge or a hypothesis is included into the logical system. Collisions indicate violations of some formal rules or restrictions providing consistency of this system.

By using collisions, NTA allows for a formal definition of hypotheses. Let us suppose that a system of premises expressed as NTA objects $A_1, A_2, \dots, A_n$ is given and the NTA object $A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$ is calculated.

Then a certain formula H is called a ***hypothesis*** under the following conditions:

- 1) $A \subseteq_G H$ is false. Otherwise, H is a consequence according to (1).
- 2) The hypothesis is correct, if the object $H \cap_G A$ contains no collisions.

The first condition can be expressed in other way: $A \setminus_G H \neq \emptyset$. The second condition assumes that the hypothesis is a premise or an axiom.

Usually, forming and checking of hypotheses accompany other analysis methods for defeasible reasoning. Below, we will describe usage of hypotheses in searching for abductive conclusions.

Abduction is forming of an explanatory hypothesis when one knows some of premises and an estimated consequence confirmed with facts or reasonable arguments, but a formal check does not infer it from the given premises. For example, abduction is used during diagnostics.

Let us now formally define abduction.

If B is an estimated consequence from the premises $A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$ and the statement $A \subseteq_G B$ is known to be false, then a formula H is an ***admissible abductive conclusion*** when the two following conditions are met:

- 1) H is a hypothesis (i.e. $A \subseteq_G H$ is false) and $H \cap_G A$ is not empty;
- 2) $(H \cap_G A) \subseteq_G B$, that is adding H into the system of premises results in deducibility of the estimated consequence B .

Considering the above definitions, we propose a search algorithm for abductive conclusions.

Consider an example. The goal is to check the correctness of inference for the following argument: “If Jones did not meet Smith that night, than either Smith was a killer, or Jones is lying. If Smith was not the killer, then Jones did not meet Smith this night and the murder happened after midnight. If the murder happened after midnight, then either Smith was the killer, or Jones is lying. Consequently, Smith was the killer”.

First, we express this argument in the language of propositional calculus. Introduce the following notation: C , Jones met Smith that night; D , Smith was the murderer; E , Jones is lying; F , the murder happened after midnight. Then, after converting each of the proposals into a DNF, we obtain the following expressions:

- for the first sentence: $C \vee (D \wedge \neg E) \vee (\neg D \wedge C)$;
- for the second sentence: $D \vee (\neg C \wedge F)$;
- for the third sentence: $\neg F \vee (D \wedge \neg E) \vee (\neg D \wedge E)$;
- for the conclusion: D .

In order to rewrite these formulas as NTA objects, we use the universe $X_C \times X_C \times X_E \times X_F = \{0, 1\}^4$ where $C = D = E = F = 1$ and $\neg C = \neg D = \neg E = \neg F = 0$. Then, the premises are expressed as the following C -systems:

$$A_1 = \begin{bmatrix} \{1\} & * & * & * \\ * & \{1\} & \{0\} & * \\ * & \{0\} & \{1\} & * \end{bmatrix}; A_2 = \begin{bmatrix} * & \{1\} & * & * \\ \{0\} & * & * & \{1\} \end{bmatrix}; A_3 = \begin{bmatrix} * & * & * & \{0\} \\ * & \{1\} & \{0\} & * \\ * & \{0\} & \{1\} & * \end{bmatrix}$$

and the conclusion is expressed as the C -n-tuple $B[X_D] = [\{1\}]$.

To solve the problem, we check the relation $(A_1 \cap_G A_2 \cap_G A_3) \subseteq_G B[X_D]$. To do this, we calculate

$$A[X_C X_D X_E X_F] = A_1 \cap_G A_2 \cap_G A_3 = \begin{bmatrix} \{1\} & \{1\} & * & \{0\} \\ * & \{1\} & \{0\} & * \\ \{0\} & \{0\} & \{1\} & \{1\} \end{bmatrix}.$$

To check the inclusion, we add the missing attributes in B : $B[X_C X_D X_E X_F] = [* \{1\} * *]$.

Verification shows that the third C -n-tuple of A is not included in B , i.e., the supposed conclusion (Smith was the killer) is not deducible. In order to confirm or refute the accuracy of the conclusion, certain circumstances must be clarified. The search for such circumstances can be formulated as the problem of finding an abductive conclusion.

Suppose that the conclusion is correct. Then, we need to find hypotheses whose addition to the premises will result in deducibility of the supposed conclusion.

To find such hypotheses, we use the algorithm proposed above:

$$R = A \setminus_G B = \begin{bmatrix} \{1\} & \{1\} & * & \{0\} \\ * & \{1\} & \{0\} & * \\ \{0\} & \{0\} & \{1\} & \{1\} \end{bmatrix} \cap_G [* \{0\} * *] = [\{0\} \{0\} \{1\} \{1\}].$$

Now, we can select any projection of R as R_i . Let it be $R[X_F]$, then $R_i = [* * * \{1\}]$, $H_i = [* * * \{0\}]$.

Since no additional restrictions are defined for this example, it is sufficient to check whether the intersection of premises becomes confluent for the chosen hypothesis:

$$A \cap_G H_i = \begin{bmatrix} \{1\} & \{1\} & * & \{0\} \\ * & \{1\} & \{0\} & * \\ \{0\} & \{0\} & \{1\} & \{1\} \end{bmatrix} \cap_G [* * * \{0\}] = \begin{bmatrix} \{1\} & \{1\} & * & \{0\} \\ * & \{1\} & \{0\} & \{0\} \end{bmatrix}.$$

Verification confirms the correctness of this hypothesis. In natural language, the tested hypothesis means that the murder happened before midnight. Hence, the conclusion would be correct if a clarification of the murder time would comply with the hypothesis.

Often, it is not sufficient to test one hypothesis for analysis of an argument. For the above example in particular, another possible hypothesis arises from selecting the projection $[X_C X_E]$. Then the conclusion would be correct, if the following hypothesis is confirmed: “Jones met Smith that night and Jones does not lie”.

MEASURES IN NTA

NTA structures consist of sets of n -tuples being Cartesian products in essence. A measure (a probabilistic measure in particular) can be easily calculated for a Cartesian product; that is why NTA structures can

be readily immersed into a space with a measure. For instance, if measures of a C - n -tuple' components are known, the measure of the C - n -tuple itself equals to the product of these measures.

For example, if the C - n -tuple $R[XYZ] = [A \ B \ C]$ is specified in measurable attributes, and the measures of its components are equal respectively $\mu(A)$, $\mu(B)$ и $\mu(C)$, then

$$\mu(R) = \mu(A) \cdot \mu(B) \cdot \mu(C).$$

It is not that easy to calculate a measure for a C -system since intersections of some its elements can be not empty. That is why we have developed algorithms to transform any NTA structure to an orthogonal C -system that has no overlapping pairs of C - n -tuples (Kulik, 2007). Then its measure equals to the sum of the measures for the C - n -tuples comprising it.

Let us introduce two possible ways to use metric properties of NTA objects.

The first way proposes the number of elementary n -tuples as a measure based on the following regularity. Let a C - n -tuple be given in a space of attributes $P = [P_1 \ P_2 \ \dots \ P_n]$ with a finite number of their values. Then the power $|P_i|$ of every component P_i is a finite number as well, and the power (that is the number of elementary n -tuples) of the C - n -tuple P equals to $|P| = |P_1| \cdot |P_2| \cdot \dots \cdot |P_n|$. By using our orthogonalization algorithm, it is possible to count the power of every NTA object that has finite sets as its components.

In particular, this approach is applicable for a quantitative estimation of logical inference. Suppose a system of premises $A_1, A_2, \dots, A_n$ is defined in a space of attributes $X_1, X_2, \dots, X_k$ with a finite number of their values. Then the number of possible consequences from these premises equals to 2^M where $M = |U| - |A|$, $U = X_1 \times X_2 \times \dots \times X_k$ and $A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n$.

This possibility to count powers of NTA objects allows for estimating an **uncertainty measure** for a consequence B_j derived from the premises $A_1, A_2, \dots, A_n$. It looks reasonable to define such a measure as the ratio $\frac{|B_j|}{|A|}$ between the power of B_j and the power of the minimal consequence

$$A = A_1 \cap_G A_2 \cap_G \dots \cap_G A_n.$$

The second way to use metric properties of NTA objects is suitable for implementation of the logic-probabilistic analysis (LPA) for systems modeled by logical functions. LPA has been developed by I. A. Ryabinin (1976) and his colleagues. To analyze safety and reliability of such systems, LPA exploits mathematical models of the propositional calculus mostly. So, these methods are good for systems with two possible states (for example, normal functioning and failure). NTA contains methods allowing to calculate probabilities in the systems where components have more than two states (Kulik, 2007).

The presented approach corresponds to the *direct problem* of LPA, when the probability of a complex event is calculated for given probabilities of elementary events. In the *inverse problem*, it is necessary to calculate probabilities of elementary events based on the data about probabilities of certain complex events. After this, one can calculate the probabilities of other complex events. Problems solved in probabilistic logic are of this type (Kulik, 2007; Nilsson, 1986).

Let us analyze an example from (Nilsson, 1986).

Assume that a totality of the given events is defined by formulas A and $A \supset B$ of propositional calculus, besides, $p(A) = p_1$ and $p(A \supset B) = p_2$. It is necessary to estimate the probability $p(B)$ for the event B .

We will solve this problem by means of NTA. Here are two logical variables A and B , which model elementary events as well. Let us suppose probabilities of these events equal to $p(A)$ and $p(B)$ correspondingly. The statement of this problem gives $p(A) = p_1$. Now we will express the given formulas in NTA structures within the universe

$$\{0, 1\}^2: A = [\{1\} *]; B = [* \{1\}]; A \supset B = \bar{A} \vee B = \{0\} \{1\} = \begin{bmatrix} \{0\} & * \\ \{1\} & \{1\} \end{bmatrix}$$

(here the D -n-tuple modeling the formula $A \supset B$ is transformed into an orthogonal C -system).

Then the probabilistic formulas for the events A and $A \supset B$ are as follows:

$$P(A) = p_1; P(A \supset B) = (1 - p(A)) + p(A)p(B) = p_2.$$

So, we have got a system of two equations:

$$p(A) = p_1; (1 - p(A)) + p(A) p(B) = p_2$$

that allows to easily conclude

$$p(B) = \frac{p_1 + p_2 - 1}{p_1}.$$

This is the precise result for this problem while N. Nilsson (1986) gives only an interval estimate for this result, namely $p_2 + p_1 - 1 \leq p(B) \leq p_2$.

METRIZATION AND CLUSTERING OF NTA OBJECTS

For the measurable logical models discussed in the previous section, it is also possible to determine the distance by which the proximity (or remoteness) of different objects is estimated. Assume we have two NTA objects R_1 and R_2 immersed into a measurable space with a measure μ . Then the distance $d(R_1, R_2)$ between them can be calculated as:

$$d(R_1, R_2) = \mu(R_1 \Delta R_2) = \mu((R_1 \setminus R_2) \cup (R_2 \setminus R_1)). \quad (2)$$

If $R_1 \subseteq R_2$, then $d(R_1, R_2) = \mu(R_2) - \mu(R_1)$. At the same time, if $R_1 \cap R_2 = \emptyset$, then $d(R_1, R_2) = \mu(R_2) + \mu(R_1)$.

The meaning of this proximity measure is that the “distance” between two NTA objects R_1 and R_2 is the smaller, the larger is the measure of the object $R_1 \cap R_2$.

Other methods to metrize NTA objects are provided for certain types of domains. These include ordered domains and interval type domains.

Consider **domains of interval type** (Kulik & Fridman, 2017). Let the domain of an attribute be defined as a closed interval Ω on a numerical axis and a finite set $E = \{E_i\}$ of closed intervals such that $\cup E_i \in \Omega$ be given. The boundaries of the intervals are given by the sets of coordinates for initial and final points. If we align all points denoting boundaries in the ascending order, we obtain a partition of the system of intervals into quanta, i.e. neighboring points and open spaces between them. The terminological difficulties associated with the fact that the set of quanta consists of dissimilar objects (points and intervals) can be circumvented by defining a point as a degenerate interval with zero measure. An example of the quantization procedure for four intervals E_1, E_2, E_3, E_4 is shown in Figure 1. For clarity, the intervals E_i are moved above the axis.

Figure 1. Quantization of a system of intervals

Here the interval Ω bounded by the points P and Q contains inner points $a, b, \dots, h$. Hence, each interval E_i contains a number of quanta. For instance, the closed interval E_3 comprises points and open intervals: $E_3 = \{c, d, e, f, (c, d), (d, e), (e, f)\}$. We can also represent E_3 as an ordered set $\{(c, d), (d, e), (e, f)\}$ of open disjoint intervals corresponding to the quanta. This way, every non-degenerate interval or non-empty result of set-theoretic operations with open intervals can be translated into an ordered set of quanta. The measure of such domains is evidently additive: the measure of an arbitrary set of quanta equals to the sum of measures for these quanta.

If an attribute domain is an **ordered set**, for example, $(a, b, c, \dots)$, we also represent it as an ordered set of quanta with names 1, 2, 3, ... If no measures of quanta are given, the measure of each quantum is assumed to be 1.

If measures of quanta are known and differ from each other (for instance, when attribute values are formed as a result of quantizing a certain set of intervals), such attributes require **normalization of intervals**, by which the average measure of all quanta becomes equal to 1. Let the measure L of an interval containing all quanta, and quantum measures l_i ($i = 1, 2, \dots, M$) be given. When normalized, **the measure of the normalized interval** is taken equal to M , and **measures of normalized quanta** (μ_i) are calculated as $\mu_i = \frac{l_i \cdot M}{L}$.

The proposed approach to defining domain measures allows to consider modeled NTA objects not only as structures immersed into a measurable space, but also as structures in a metric space. In a measurable space with domain measures, which admit using the methods outlined in the previous section, we can calculate measures of arbitrary NTA objects and their proximity by the formula (2).

If the considered model is used for solving the problem of transition to a metric space in which it is necessary to apply clustering methods, no transformations are required, it is sufficient to assume that measures of domains and their quanta defined above characterize distances.

FUTURE RESEARCH DIRECTIONS

In the authors' opinion regarding NTA development, future research ought to include the following directions: context-oriented database (knowledge base) management systems; additional means of immersing NTA structures into measure spaces and assigning NTA objects with quantitative features; modeling

dynamic intelligent systems (Vinogradov, Zhilyakova, & Osipov, 2002) within the situational approach; applications NTA methods to smart electromechanical systems (SEMS) (Kulik & Fridman, 2016).

CONCLUSION

This paper introduces a new mathematical instrument, n -tuple algebra (NTA) that implements an algebraic approach to the general theory of n -ary relations. Unlike relational algebra and theory of binary relations, NTA uses Cartesian product of sets rather than elementary n -tuples as a basic structure and is based on some generalized operations and relations. They provide logical processing of relations with different relation diagrams; these methods have no analogies in convenient theories. NTA belongs to the class of Boolean algebras. It is proved to be isomorphic to algebra of sets and supports unified implementation of various data/knowledge structures typical for artificial intelligence and many techniques of their semantic and logical analyses. Matrix properties of NTA objects allow decreasing complexity of intellectual procedures for some new structural and statistical classes of CNFs with polynomially identifiable satisfiability as well as by efficient parallelization of logical inference algorithms. NTA structures can be readily immersed into spaces with a measure. In particular, some new solutions were found for the direct and inverse problems of the logic-probabilistic analysis. Besides, the proposed approach makes it possible to use clustering methods in models of knowledge bases.

KEY TERMS AND DEFINITIONS

C-n-Tuple: An n -tuple of components defined in a certain relation diagram; domain of each component is a subset of the domain of the corresponding attribute.

C-System: A set of homotypic C - n -tuples that are denoted as a matrix in square brackets and equal to the intersection of these C - n -tuples. The rows of this matrix are C - n -tuples.

Collisions: Situations occurring during defeasible reasoning when some new knowledge (hypothesis) is inputted. Such situations can be recognized as violations of some formally expressed rules and/or limitations which control consistency and meaning content of a logical system.

D - n -Tuple: An n -tuple of components enclosed in reversed square brackets and equal to a diagonal C -system with the same diagonal components.

D -System: A set of homotypic D - n -tuples equal to the intersection of these D - n -tuples.

Generalized Operations and Relations: They differ from similar operations and relations of algebra of sets by the only feature: NTA objects (operands) are reduced to the same relation diagram before executing these operations or checking the relations.

N -Tuple Algebra: An algebraic system whose support is an arbitrary set of n -ary relations expressed by specific structures, namely, C - n -tuple, C -system, D - n -tuple, and D -system. These structures provide a compact expression for sets of elementary n -tuples.

Intelligent Constructing Exact Tolerance Limits for Prediction of Future Outcomes Under Parametric Uncertainty

Nicholas Nechval

University of Latvia, Latvia

INTRODUCTION

The logical purpose for a statistical tolerance limit (where the coverage value γ is the percentage of the future process outcomes to be captured by the prediction, and the confidence level $(1-\alpha)$ is the proportion of the time we hope to capture that percentage γ) is to predict future outcomes for some production process which is treated as process, say, with stochastic variation of a product lifetime. The applications of tolerance limits (intervals) are varied. They included clinical and industrial applications, including quality control, applications to environmental monitoring, to the assessment of agreement between two methods or devices, and applications in industrial hygiene. For example, such tolerance limits are required, when planning life tests, engineers may need to predict the number of failures that will occur by the end of the test or to predict the amount of time that it will take for a specified number of units to fail. Tolerance limits of the type mentioned above are considered in this article, which presents a new technique for constructing exact statistical (lower and upper) tolerance limits on outcomes (for example, on order statistics) in future samples. Attention is restricted to the extreme-value and two-parameter Weibull distributions under parametric uncertainty (when both parameters are unknown). The technique used here emphasizes pivotal quantities relevant for obtaining tolerance factors and is applicable whenever the statistical problem is invariant under a group of transformations that acts transitively on the parameter space. It does not require the construction of any tables and is applicable whether the experimental data are complete or Type II censored. The exact tolerance limits on order statistics associated with sampling from underlying distributions can be found easily and quickly making tables, simulation, Monte Carlo estimated percentiles, special computer programs, and approximation unnecessary. The proposed technique is based on a probability transformation and pivotal quantity averaging. It does not in need to make any assumption concerning the statistical functional form for the tolerance limit, is conceptually simple and easy to use. The scientific literature does not contain an analytical methodology for constructing exact γ -content tolerance limits with expected $(1-\alpha)$ -confidence on future order statistics coming from an extreme-value or Weibull distribution. One reason is that the theoretical concept and computational complexity of the tolerance limits is significantly more difficult than that of the standard confidence and prediction limits. However, in the literature there are several known methods for constructing $(1-\alpha)$ -prediction limits (in terms of this article, tolerance limits with expected $(1-\alpha)$ -confidence) on future order statistics coming from the two-parameter Weibull distribution. Therefore, finally, we give numerical examples, where the $(1-\alpha)$ -prediction limits obtained by using the known methods are compared with the results obtained through the proposed analytical methodology, which is illustrated in terms of the extreme-value and two-parameter Weibull distributions. Analytical formulas for the tolerance limits are available in the scientific literature for only simple cases, for example, for the upper or lower tolerance

DOI: 10.4018/978-1-7998-3479-3.ch049

limit for a univariate normal population. Thus it becomes necessary to use new methods in order to derive exact statistical tolerance limits for many populations. The proposed, in this article, technique of intelligent constructing exact statistical γ -content tolerance limits with expected $(1-\alpha)$ -confidence, which are obtained here in terms of the two-parameter Weibull and extreme-value distributions, represents a novelty in the theory of statistical decisions.

BACKGROUND

In this paper, two types of statistical tolerance limits are defined: i) γ -content tolerance limits with expected $(1-\alpha)$ -confidence on future outcomes, ii) tolerance limits with expected $(1-\alpha)$ -confidence on future outcomes. To be specific, let γ denote a proportion between 0 and 1. Then one-sided statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence is determined to capture a proportion γ or more of the population, with a given expected confidence level $1-\alpha$. For example, an upper statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence on future outcomes from a univariate population is such that with the given expected confidence level $1-\alpha$, a specified proportion γ or more of the population will fall below the limit. A lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence satisfies similar conditions. An upper statistical tolerance limit with expected $(1-\alpha)$ -confidence is determined so that the expected proportion of the population failing below the limit is $(1-\alpha)$. A lower statistical tolerance limit with expected $(1-\alpha)$ -confidence satisfies similar conditions. The statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence seems to be more useful than the statistical tolerance limit with expected $(1-\alpha)$ -confidence but is relatively difficult to construct.

The logical purpose for a tolerance limit must be the prediction of future outcomes for some (say, stochastic) process. Tolerance (prediction) limits enjoy a fairly rich history in the scientific literature and have a very important role in engineering and manufacturing applications. Patel (1986) provides a review (which was fairly comprehensive at the time of publication) of tolerance intervals (limits) for many distributions as well as a discussion of their relation with confidence intervals (limits) for percentiles. Dunsmore (1978) and Guenther, Patil, and Uppuluri (1976) both discuss 2-parameter exponential tolerance intervals (limits) and the estimation procedure in greater detail. Engelhardt and Bain (1978) discuss how to modify the formulas when dealing with type II censored data. Guenther (1972) and Hahn and Meeker (1991) discuss how one-sided tolerance limits can be used to obtain approximate two-sided tolerance intervals by applying Bonferroni's inequality. In Nechval et al. (1999, 2004, 2014a, 2016a, 2016b, 2016c, 2017, 2018a, 2019), the exact statistical tolerance and prediction limits are discussed under parametric uncertainty of underlying models.

In contrast to other statistical limits commonly used for statistical inference, the γ -content tolerance limits with expected $(1-\alpha)$ -confidence (especially for the order statistics) are used relatively rarely. One reason is that the theoretical concept and computational complexity of the γ -content tolerance limits with expected $(1-\alpha)$ -confidence is significantly more difficult than that of the standard confidence and prediction limits. Thus it becomes necessary to use the innovative approaches which will allow one to construct tolerance limits on future order statistics for many populations.

FOCUS OF THE ARTICLE

Problem Statement

The problem can be stated more formally as follows. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable X from a sample of size n from a distribution with a probability density function $f_{\theta}(x)$ (distribution function $F_{\theta}(x)$, survival function $\bar{F}_{\theta}(x) = 1 - F_{\theta}(x)$) and S be any statistic (say, sufficient statistic or maximum likelihood estimator) obtained from the experimental random sample $X_1 \leq \dots \leq X_r$ and let a random variable Y (in a future random sample $Y_1, \dots, Y_m$) has the same distribution with the probability density function $f_{\theta}(y)$ (distribution function $F_{\theta}(y)$, survival function $\bar{F}_{\theta}(y) = 1 - F_{\theta}(y)$), where a parameter θ (in general, vector) is common to both distributions and it is assumed that some or all numerical values of components of the parametric vector θ are unspecified.

On the basis of the experimental random sample $X_1 \leq \dots \leq X_r$ we wish to make a prediction about a future outcome of Y_k (k th order statistic, $1 \leq k \leq m$, in a future random sample of m ordered observations $Y_1 \leq \dots \leq Y_m$), usually in the form of one-sided statistical tolerance limits on future outcomes of Y_k (lower γ -content tolerance limit L_k with expected $(1-\alpha)$ -confidence and upper γ -content tolerance limit U_k with expected $(1-\alpha)$ -confidence). That is, if L_k and U_k are functions of S , then $L_k \equiv L_k(S)$ is a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence on future outcomes of the k th order statistic Y_k if

$$E_{\theta} \left\{ \Pr \left(\int_{L_k(S)}^{\infty} g_{\theta}(y_k) dy_k \geq \gamma \right) \right\} = E_{\theta} \left\{ \Pr \left(\bar{G}_{\theta}(L_k(S)) \geq \gamma \right) \right\} = 1 - \alpha, \quad (1)$$

and $U_k \equiv U_k(S)$ is an upper statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence on future outcomes of the k th order statistic Y_k if

$$E_{\theta} \left\{ \Pr \left(\int_0^{U_k(S)} g_{\theta}(y_k) dy_k \geq \gamma \right) \right\} = E_{\theta} \left\{ \Pr \left(G_{\theta}(U_k(S)) \geq \gamma \right) \right\} = 1 - \alpha, \quad (2)$$

where

$$g_{\theta}(y_k) = \frac{1}{B(k, m-k+1)} [F_{\theta}(y_k)]^{k-1} [1 - F_{\theta}(y_k)]^{m-k} f_{\theta}(y_k) \quad (3)$$

is the probability density function of the k th order statistic Y_k ,

$$\begin{aligned} G_{\theta}(y_k) &= \Pr(Y_k \leq y_k) = \sum_{i=k}^m \binom{m}{i} [F_{\theta}(y_k)]^i [1 - F_{\theta}(y_k)]^{m-i} = \sum_{i=k}^m \binom{m}{i} [1 - \bar{F}_{\theta}(y_k)]^i [\bar{F}_{\theta}(y_k)]^{m-i} \\ &= \sum_{i=k}^m \binom{m}{i} \sum_{j=0}^i \binom{i}{j} (-1)^j [\bar{F}_{\theta}(y_k)]^{m-i+j} = \int_0^{F_{\theta}(y_k)} \frac{1}{B(k, m-k+1)} \tau^{k-1} (1-\tau)^{m-k} d\tau \end{aligned} \quad (4)$$

is the probability distribution function of the k th order statistic Y_k . It can be shown that

$$\frac{dG_{\theta}(y_k)}{dy_k} = g_{\theta}(y_k). \quad (5)$$

Further, $L_k^{\circ} \equiv L_k^{\circ}(S)$ is a lower statistical tolerance limit with expected $(1-\alpha)$ -confidence on future outcomes of the k th order statistic Y_k from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ if it satisfies

$$E_{\theta} \left\{ \Pr(Y_k > L_k^{\circ}(S)) \right\} = E_{\theta} \left\{ \int_{L_k^{\circ}(S)}^{\infty} g_{\theta}(y_k) dy_k \right\} = E_{\theta} \left\{ \bar{G}_{\theta}(L_k^{\circ}(S)) \right\} = 1 - \alpha. \quad (6)$$

$U_k^{\circ} \equiv U_k^{\circ}(S)$ is an upper statistical tolerance limit with expected $(1-\alpha)$ -confidence on future outcomes of the k th order statistic Y_k from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ if it satisfies

$$E_{\theta} \left\{ \Pr(Y_k \leq U_k^{\circ}(S)) \right\} = E_{\theta} \left\{ \int_0^{U_k^{\circ}(S)} g_{\theta}(y_k) dy_k \right\} = E_{\theta} \left\{ G_{\theta}(U_k^{\circ}(S)) \right\} = 1 - \alpha. \quad (7)$$

In this article, a new technique for intelligent constructing the statistical γ -content tolerance limits with expected $(1-\alpha)$ -confidence as well as the statistical tolerance limits with expected $(1-\alpha)$ -confidence on order statistics in future samples is proposed. For illustration, the extreme-value and Weibull distributions are considered.

Extreme-Value Distribution

This distribution is used in many research fields including, among others, life testing and water resource management. This is the so-called first asymptotic distribution of extreme values, hereafter referred to simply as the extreme-value distribution. The distribution is extensively used in a number of areas as a lifetime distribution and sometimes referred to as the Gumbel distribution, after E. J. Gumbel, who had pioneered its use (Gumbel, 1958).

Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable X from a sample of size n from an extreme-value distribution with the pdf (probability density function),

$$f_{\theta}(x) = \frac{1}{\theta_2} \exp\left(\frac{x - \theta_1}{\theta_2}\right) \exp\left[-\exp\left(\frac{x - \theta_1}{\theta_2}\right)\right], \quad -\infty < x < \infty, \quad (8)$$

and cdf (cumulative distribution function),

$$F_{\theta}(x) = 1 - \exp\left[-\exp\left(\frac{x - \theta_1}{\theta_2}\right)\right], \quad -\infty < x < \infty, \quad (9)$$

indexed by location and scale parameters θ_1 and θ_2 , where $\theta = (\theta_1, \theta_2)$. It is assumed that the parameters $\theta_1 (-\infty < \theta_1 < \infty)$ and $\theta_2 > 0$ are unknown.

In Type II censoring, which is of primary interest here, the number of survivors are fixed and X_r is a random variable. The MLE's $\hat{\theta}_1$ and $\hat{\theta}_2$ of the parameters θ_1 and θ_2 , respectively, are solutions of

$$\hat{\theta}_1 = \ln \left[r^{-1} \left(\sum_{i=1}^r \exp \left(\frac{x_i}{\hat{\theta}_2} \right) + (n-r) \exp \left(\frac{x_r}{\hat{\theta}_2} \right) \right) \right]^{\hat{\theta}_2}, \quad (10)$$

$$\hat{\theta}_2 = \left[\sum_{i=1}^r x_i \exp \left(\frac{x_i}{\hat{\theta}_2} \right) + (n-r) x_r \exp \left(\frac{x_r}{\hat{\theta}_2} \right) \right] \left[\sum_{i=1}^r \exp \left(\frac{x_i}{\hat{\theta}_2} \right) + (n-r) \exp \left(\frac{x_r}{\hat{\theta}_2} \right) \right]^{-1} - \frac{1}{r} \sum_{i=1}^r x_i. \quad (11)$$

In terms of the extreme-value distribution variates, we have that

$$W_1 = \frac{\hat{\theta}_1 - \theta_1}{\theta_2}, \quad W_2 = \frac{\hat{\theta}_2}{\theta_2}, \quad W_3 = \frac{\hat{\theta}_1 - \theta_1}{\hat{\theta}_2} \quad (12)$$

are pivotal quantities. The probability density functions of the pivotal quantities do not depend on the parameters. It can be shown that the joint pdf of the pivotal quantities

$$W_1 = \frac{\hat{\theta}_1 - \theta_1}{\theta_2}, \quad W_2 = \frac{\hat{\theta}_2}{\theta_2}, \quad (13)$$

conditional on fixed

$$\mathbf{S}^{(r)} = (S_r, \dots, S_r), \quad (14)$$

where

$$S_i = \frac{X_i - \hat{\theta}_1}{\hat{\theta}_2}, \quad i = 1, \dots, r, \quad (15)$$

are ancillary statistics, any $r-2$ of which form a functionally independent set, $\hat{\theta}_1$ and $\hat{\theta}_2$ are the maximum likelihood estimates for θ_1 and θ_2 , respectively, based on the first r ordered observations ($X_1 \leq \dots \leq X_r$) from a sample of size n from the extreme-value distribution (8), which can be found from solution of (10) and (11), is given by

$$\begin{aligned}
 & f_n(w_1, w_2 | \mathbf{s}^{(r)}) \\
 &= \left(\frac{(e^{w_1})^r}{\Gamma(r)} \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^r \exp \left(-e^{w_1} \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right] \right) \right) \\
 &\times \left(\frac{1}{v(\mathbf{s}^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} \right) \\
 &= f_n(w_1 | \mathbf{s}^{(r)}, w_2) f_n(w_2 | \mathbf{s}^{(r)}), w_1 \in (-\infty, \infty), w_2 \in (0, \infty),
 \end{aligned} \tag{16}$$

where

$$\begin{aligned}
 f_n(w_1 | \mathbf{s}^{(r)}, w_2) &= \frac{(e^{w_1})^r}{\Gamma(r)} \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^r \\
 &\exp \left(-e^{w_1} \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right] \right), w_1 \in (-\infty, \infty).
 \end{aligned} \tag{17}$$

$$f_n(w_2 | \mathbf{s}^{(r)}) = \frac{1}{v(\mathbf{s}^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r}, w_2 \in (0, \infty), \tag{18}$$

$$v(\mathbf{s}^{(r)}) = \int_0^\infty w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} dw_2 \tag{19}$$

is the normalizing constant. If a pivotal quantity is given by

$$W = e^{W_1} \left[\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2) \right], \tag{20}$$

it follows from (17) that

$$W \sim g_r(w) = \frac{1}{\Gamma(r)} w^{r-1} \exp(-w), w \in (0, \infty). \tag{21}$$

Two-Parameter Weibull Distribution

The two-parameter Weibull distribution is one of the most widely used life distributions in reliability analysis. This distribution is very flexible, and can, through an appropriate choice of parameters, model many types of failure rate behaviors. It has wide applications in diverse disciplines.

Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable X from a sample of size n from a two-parameter Weibull distribution with the pdf,

$$f_{\theta}(\underline{x}) = \frac{\delta}{\beta} \left(\frac{\underline{x}}{\beta} \right)^{\delta-1} \exp \left[- \left(\frac{\underline{x}}{\beta} \right)^{\delta} \right], \quad \underline{x} > 0, \quad \beta > 0, \quad \delta > 0, \quad (22)$$

and cdf,

$$F_{\theta}(\underline{x}) = 1 - \exp \left[- \left(\frac{\underline{x}}{\beta} \right)^{\delta} \right], \quad \underline{x} > 0, \quad \beta > 0, \quad \delta > 0, \quad (23)$$

indexed by scale and shape parameters β and δ , where $\theta = (\beta, \delta)$. It is assumed that the parameters β and δ are unknown. This distribution is directly related to the extreme-value distribution by the easily shown fact that if X has a Weibull distribution (22), then $X = \ln X$ has an extreme-value distribution with $\theta_1 = \ln \beta$ and $\theta_2 = \delta^{-1}$. In analyzing data it is often convenient to work with log times, the extreme-value distribution arises when lifetimes are taken to be Weibull distributed. The MLE's of the Weibull parameters β and δ are $\hat{\beta} = \exp \hat{\theta}_1$ and $\hat{\delta} = \hat{\theta}_2^{-1}$. If desired, the maximum likelihood equations (10) and (11) can be written in Weibull form and solved directly from the start. The equations are

$$\hat{\beta} = \left(r^{-1} \left(\sum_{i=1}^r x_i^{\hat{\delta}} + (n-r) \underline{x}_r^{\hat{\delta}} \right) \right)^{1/\hat{\delta}}, \quad (24)$$

$$\hat{\delta} = \left[\left(\sum_{i=1}^r \underline{x}_i^{\hat{\delta}} \ln \underline{x}_i + (n-r) \underline{x}_r^{\hat{\delta}} \ln \underline{x}_r \right) \left(\sum_{i=1}^r \underline{x}_i^{\hat{\delta}} + (n-r) \underline{x}_r^{\hat{\delta}} \right)^{-1} - \frac{1}{r} \sum_{i=1}^r \ln \underline{x}_i \right]^{-1}. \quad (25)$$

In terms of the Weibull variates, we have that

$$V_1 = \left(\frac{\hat{\beta}}{\beta} \right)^{\delta}, \quad V_2 = \frac{\delta}{\hat{\delta}}, \quad V_3 = \left(\frac{\hat{\beta}}{\beta} \right)^{\hat{\delta}} \quad (26)$$

are pivotal quantities. The probability density functions of the pivotal quantities do not depend on the parameters. It can be shown that the joint pdf of the pivotal quantities

$$V_1 = \left(\frac{\hat{\beta}}{\beta} \right)^\delta, \quad V_2 = \frac{\delta}{\hat{\delta}}, \quad (27)$$

conditional on fixed

$$\mathbf{Z}^{(r)} = (Z_1, \dots, Z_r), \quad (28)$$

where

$$Z_i = \left(\frac{X_i}{\beta} \right)^\delta, \quad i = 1, \dots, r, \quad (29)$$

are ancillary statistics, any $r-2$ of which form a functionally independent set, $\hat{\beta}$ and $\hat{\delta}$ are the maximum likelihood estimates for β and δ , respectively, based on the first r ordered observations $X_1 \leq \dots \leq X_r$ from a sample of size n from the two-parameter Weibull distribution (22), which can be found from solution of (24) and (25), is given by

$$\begin{aligned} f_n(v_1, v_2 | \mathbf{z}^{(r)}) &= \left(\frac{v_1^{r-1}}{\Gamma(r)} \left[\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right]^r \exp \left(-v_1 \left[\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right] \right) \right) \\ &\times \left(\frac{1}{g(\mathbf{z}^{(r)})} v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left[\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right]^{-r} \right) = f_n(v_1 | \mathbf{z}^{(r)}, v_2) f_n(v_2 | \mathbf{z}^{(r)}), \end{aligned} \quad (30)$$

$v_1 \in (0, \infty), \quad v_2 \in (0, \infty),$

where

$$f_n(v_1 | \mathbf{z}^{(r)}, v_2) = \frac{1}{\Gamma(r)} \left[\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right]^r v_1^{r-1} \exp \left(-v_1 \left[\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right] \right), \quad v_1 \in (0, \infty), \quad (31)$$

$$f_n(v_2 | \mathbf{z}^{(r)}) = \frac{1}{g(\mathbf{z}^{(r)})} v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)^{-r}, \quad v_2 \in (0, \infty), \quad (32)$$

$$g(\mathbf{z}^{(r)}) = \int_0^\infty v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)^{-r} dv_2 \quad (33)$$

is the normalizing constant. If a pivotal quantity is given by

$$V = V_1 \left[\sum_{i=1}^r Z_i^{V_2} + (n-r)Z_r^{V_2} \right], \quad (34)$$

it follows from (31) that

$$V \sim g_r(v) = \frac{1}{\Gamma(r)} v^{r-1} \exp(-v), \quad v \in (0, \infty). \quad (35)$$

CONSTRUCTING STATISTICAL γ -CONTENT TOLERANCE LIMITS WITH EXPECTED $(1-\alpha)$ -CONFIDENCE

Constructing Lower Statistical γ -Content Tolerance Limit with Expected $(1-\alpha)$ -Confidence

Theorem 1. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\ln \underline{X})$ from a sample of size n from an extreme-value distribution defined by the probability density function (8). Then a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $L_k \equiv L_k(S)$, on future outcomes of the k th order statistic $Y_k(=\ln Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (8), which satisfies (1) is given by

$$L_k = \hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{L_k} = \ln \underline{L}_k, \quad (36)$$

where η_{L_k} is a tolerance factor determined by

$$\eta_{L_k} = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right)}{[\eta_{L_k}]^{w_2}} \frac{1}{\Gamma(r)} w^{r-1} \exp(-w) \right. \\ \left. \times \frac{1}{v(s^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} dw dw_2 = 1 - \alpha \right); \quad (37)$$

the maximum likelihood estimates $\hat{\theta}_1$ and $\hat{\theta}_2$ of the parameters θ_1 and θ_2 are determined from (10) and (11), respectively; the ancillary statistics S_i , $i=1, \dots, r$, are given by (15); $q_{1-\gamma}$ is a quantile of the beta distribution satisfying

$$\int_0^{q_{1-\gamma}} \frac{1}{B(k, m-k+1)} \tau^{k-1} (1-\tau)^{m-k} d\tau = 1 - \gamma. \quad (38)$$

Proof. It follows from (3) and (4) that $\Pr\left(\int_{L_k}^{\infty} g_{\theta}(y_k) dy_k \geq \gamma\right)$

$$\begin{aligned}
 &= \Pr\left(\bar{G}_{\theta}(L_k) \geq \gamma\right) = \Pr\left(1 - G_{\theta}(L_k) \geq \gamma\right) = \Pr\left(1 - \int_0^{F_{\theta}(L_k)} \frac{1}{B(k, m-k+1)} \tau^{k-1} (1-\tau)^{m-k} d\tau \geq \gamma\right) \\
 &= \Pr\left(\int_0^{F_{\theta}(L_k)} \frac{1}{B(k, m-k+1)} \tau^{k-1} (1-\tau)^{m-k} d\tau \leq 1-\gamma\right) = \Pr\left(F_{\theta}(L_k) \leq q_{1-\gamma}\right) \\
 &= \Pr\left(1 - \exp\left[-\exp\left(\frac{L_k - \theta_1}{\theta_2}\right)\right] \leq q_{1-\gamma}\right) = \Pr\left(\exp\left[-\exp\left(\frac{L_k - \theta_1}{\theta_2}\right)\right] \geq 1 - q_{1-\gamma}\right) = \Pr\left(e^{W_1} \leq \frac{\ln(1 - q_{1-\gamma})^{-1}}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{W_2}}\right) \\
 &= \Pr\left(e^{W_1} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2)\right) \leq \frac{\ln(1 - q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2)\right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{W_2}}\right) \\
 &= \Pr\left(W \leq \frac{\ln(1 - q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2)\right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{W_2}}\right). \tag{39}
 \end{aligned}$$

Using pivotal quantity averaging, it follows from (1) and (39) that

$$\begin{aligned}
 E_{\theta} \left\{ \Pr\left(\int_{L_k(S)}^{\infty} g_{\theta}(y_k) dy_k \geq \gamma\right) \right\} &= E \left\{ \Pr\left(W \leq \frac{\ln(1 - q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2)\right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{W_2}}\right) \right\} \\
 &= E \left\{ \int_0^{\frac{\ln(1 - q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2)\right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{w_2}}} g_r(w) dw \right\} = \int_0^{\infty} \int_0^{\frac{\ln(1 - q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2)\right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2)\right]^{w_2}}} g_r(w) f_n(v_2 | \mathbf{z}^{(r)}) dw dv_2
 \end{aligned}$$

$$\begin{aligned}
&= \int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2) \right]^{w_2}} \frac{1}{\Gamma(r)} w^{r-1} \exp(-w) \\
&\times \frac{1}{v(\mathbf{s}^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} dw dw_2 = 1 - \alpha. \quad (40)
\end{aligned}$$

It follows from (40) that

$$\begin{aligned}
L_k = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right)}{\left[\exp((L_k - \hat{\theta}_1)/\hat{\theta}_2) \right]^{w_2}} \frac{1}{\Gamma(r)} w^{r-1} \exp(-w) \right. \\
\left. \times \frac{1}{v(\mathbf{s}^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} dw dw_2 = 1 - \alpha \right). \quad (41)
\end{aligned}$$

Assuming that

$$\exp\left(\frac{L_k - \hat{\theta}_1}{\hat{\theta}_2}\right) = \eta_{L_k}, \quad (42)$$

we have (36). This completes the proof.

Theorem 2. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\exp X)$ from a sample of size n from a two-parameter Weibull distribution defined by the probability density function (22). Then a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k \equiv L_k(\mathcal{S})$, on future outcomes of the k th order statistic $Y_k(\exp Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (22), which satisfies (1) is given by

$$\underline{L}_k = \eta_{\underline{L}_k}^{1/\hat{\delta}} \hat{\beta} = \exp L_k, \quad (43)$$

where $\eta_{\underline{L}_k}$ is a tolerance factor determined by

$$\eta_{L_k} = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)}{[\eta_{L_k}]^{v_2}} \frac{1}{\Gamma(r)} v^{r-1} \exp(-v) \frac{1}{g(\mathbf{z}^{(r)})} v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)^{-r} dv dv_2 = 1 - \alpha \right); \quad (44)$$

the maximum likelihood estimates $\hat{\beta}$ and $\hat{\delta}$ of the parameters β and δ are determined from (24) and (25), respectively; the ancillary statistics Z_i , $i=1, \dots, r$, are given by (29); $q_{1-\gamma}$ is a quantile of the beta distribution satisfying (38).

Proof. The proof is similar to that of Theorem 1 and so it is omitted here.

Inference 1 (for the tolerance factors η_{L_k} and η_{U_k}). It follows from (42) and (43) that

$$\eta_{L_k} = \left(\frac{L_k}{\hat{\beta}} \right)^{\hat{\delta}} = \left(\frac{\exp L_k}{\exp \hat{\theta}_1} \right)^{1/\hat{\theta}_2} = \exp \left(\frac{L_k - \hat{\theta}_1}{\hat{\theta}_2} \right) = \eta_{L_k}. \quad (45)$$

Constructing Upper Statistical γ -Content Tolerance Limit with Expected $(1-\alpha)$ -Confidence

Theorem 3. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\ln X)$ from a sample of size n from an extreme-value distribution defined by the probability density function (8). Then an upper statistical γ -content tolerance limit with $(1-\alpha)$ -confidence, $U_k \equiv U_k(S)$, on future outcomes of the k th order statistic $Y_k(=\ln Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (8), which satisfies (2) is given by

$$U_k = \hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{U_k} = \ln U_k, \quad (46)$$

where η_{U_k} is a tolerance factor determined by

$$\eta_{U_k} = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_\gamma)^{-1} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right)}{[\eta_{U_k}]^{w_2}} \frac{1}{\Gamma(r)} w^{r-1} \exp(-w) \right. \\ \left. \times \frac{1}{v(\mathbf{s}^{(r)})} w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2) \left[\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right]^{-r} dw dw_2 = \alpha \right); \quad (47)$$

the maximum likelihood estimates $\hat{\theta}_1$ and $\hat{\theta}_2$ of the parameters θ_1 and θ_2 are determined from (10) and (11), respectively; the ancillary statistics S_i , $i=1, \dots, r$, are given by (15); q_γ is a quantile of the beta distribution satisfying (38).

Proof. The upper statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $U_k \equiv U_k(S)$, is obtained from a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $L_k \equiv L_k(S)$, by replacing γ by $1-\gamma$, and $1-\alpha$ by α . This completes the proof.

Theorem 4. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\exp X)$ from a sample of size n from a two-parameter Weibull distribution defined by the probability density function (22). Then an upper statistical γ -content tolerance limit with $(1-\alpha)$ -confidence, $\underline{U}_k \equiv \underline{U}_k(S)$, on future outcomes of the k th order statistic $Y_k(=\exp Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (22), which satisfies (2) is given by

$$\underline{U}_k = \eta_{\underline{U}_k}^{1/\hat{\delta}} \hat{\beta} = \exp U_k, \quad (48)$$

where $\eta_{\underline{U}_k}$ is a tolerance factor determined by

$$\eta_{\underline{U}_k} = \arg \left[\int_0^\infty \int_0^\infty \frac{\ln(1-q_\gamma)^{-1} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)}{[\eta_{\underline{U}_k}]^{v_2}} \frac{1}{\Gamma(r)} v^{r-1} \exp(-v) \frac{1}{g(\mathbf{z}^{(r)})} v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)^{-r} dv dv_2 = \alpha \right]. \quad (49)$$

Proof. The upper statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{U}_k \equiv \underline{U}_k(S)$, is obtained from a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $L_k \equiv L_k(S)$, by replacing γ by $1-\gamma$, and $1-\alpha$ by α . This completes the proof.

Inference 2 (for the tolerance factors $\eta_{\underline{U}_k}$ and η_{U_k}). It follows from (46) and (48) that

$$\eta_{\underline{U}_k} = \left(\frac{\underline{U}_k}{\hat{\beta}} \right)^{\hat{\delta}} = \left(\frac{\exp U_k}{\exp \hat{\theta}_1} \right)^{1/\hat{\theta}_2} = \exp \left(\frac{U_k - \hat{\theta}_1}{\hat{\theta}_2} \right) = \eta_{U_k}. \quad (50)$$

CONSTRUCTING STATISTICAL TOLERANCE LIMITS WITH EXPECTED (1- α)-CONFIDENCE

Constructing Lower Statistical Tolerance Limit with Expected (1- α)-Confidence

Theorem 5. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\ln X)$ from a sample of size n from an extreme-value distribution defined by the probability density function (8). Then a lower statistical tolerance limit with expected (1- α)-confidence, $L_k^\circ \equiv L_k^\circ(S)$, on future outcomes of the k th order statistic $Y_k(=\ln L_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (8), which satisfies (6) is given by

$$L_k^\circ = \hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{L_k^\circ} = \ln \underline{L}_k^\circ, \quad (51)$$

where $\eta_{L_k^\circ}$ is a tolerance factor determined by

$$\eta_{L_k^\circ} = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{v(\mathbf{s}^{(r)})} \int_0^\infty \frac{w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2)}{\left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) + [\eta_{L_k^\circ}]^{w_2} \right)^r (m-l+j)} dw_2 = 1 - \alpha \right). \quad (52)$$

Proof. It follows from (3) and (4) that

$$\begin{aligned} \Pr(Y_k > L_k^\circ) &= \int_{L_k^\circ}^\infty g_\theta(y_k) dy_k = \bar{G}_\theta(L_k^\circ) = \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j [\bar{F}_\theta(L_k^\circ)]^{m-l+j} \\ &= \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \left(\exp \left[-\exp \left(\frac{L_k^\circ - \theta_1}{\theta_2} \right) \right] \right)^{m-l+j} = \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \\ &\times \left(\exp \left[-e^{w_1} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2) \right) \right] \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{W_2} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2) \right)^{-1} \right)^{m-l+j} \\ &= \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \left(\exp \left[-W \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{W_2} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2) \right)^{-1} (m-l+j) \right] \right). \end{aligned} \quad (53)$$

Using pivotal quantity averaging, it follows from (6) and (53) that $E_\theta \left\{ \Pr(Y_k > L_k^\circ(S)) \right\}$

$$\begin{aligned}
&= E \left\{ \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \left[\exp \left[-W \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{w_2} \left(\sum_{i=1}^r \exp(S_i W_2) + (n-r) \exp(S_r W_2) \right)^{-1} (m-l+j) \right] \right] \right\} \\
&= \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \\
&\quad \times \int_0^\infty \int_0^\infty \exp \left[-w \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{w_2} \left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) \right)^{-1} (m-l+j) \right] g_r(w) f_n(w_2 | \mathbf{s}^{(r)}) dw dw_2 \\
&= \sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{v(\mathbf{s}^{(r)})} \int_0^\infty \frac{w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2)}{\left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) + \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{w_2} (m-l+j) \right)^r} dw_2 = 1 - \alpha.
\end{aligned} \tag{54}$$

It follows from (54) that

$$\begin{aligned}
L_k^\circ = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{v(\mathbf{s}^{(r)})} \right. \\
\left. \times \int_0^\infty \frac{w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2)}{\left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) + \left(\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) \right)^{w_2} (m-l+j) \right)^r} dw_2 = 1 - \alpha \right).
\end{aligned} \tag{55}$$

Assuming that

$$\exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) = \eta_{L_k^\circ}, \tag{56}$$

we have (51). This completes the proof.

Theorem 6. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(= \exp X)$ from a sample of size n from a two-parameter Weibull distribution defined by the probability density function

(22). Then a lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^\circ \equiv \underline{L}_k^\circ(S)$, on future outcomes of the k th order statistic $Y_k(=\exp Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (22), which satisfies (6) is given by

$$\underline{L}_k^\circ = \eta_{\underline{L}_k^\circ}^{1/\hat{\delta}} \hat{\beta} = \exp L_k^\circ, \quad (57)$$

where $\eta_{\underline{L}_k^\circ}$ is a tolerance factor determined by

$$\eta_{\underline{L}_k^\circ} = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{g(\mathbf{z}^{(r)})} \int_0^\infty \frac{v_2^{r-2} \prod_{i=1}^r z_i^{v_2}}{\left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} + [\eta_{\underline{L}_k^\circ}]^{v_2} (m-l+j) \right)^r} dv_2 = 1-\alpha \right). \quad (58)$$

Proof. The proof is similar to that of Theorem 5 and so it is omitted here.

Inference 3 (for the tolerance factors $\eta_{\underline{L}_k^\circ}$ and $\eta_{\underline{L}_k^\circ}$). It follows from (56) and (57) that

$$\eta_{\underline{L}_k^\circ} = \left(\frac{\underline{L}_k^\circ}{\hat{\beta}} \right)^{\hat{\delta}} = \left(\frac{\exp L_k^\circ}{\exp \hat{\theta}_1} \right)^{1/\hat{\theta}_2} = \exp \left(\frac{L_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) = \eta_{\underline{L}_k^\circ}. \quad (59)$$

Constructing Upper Statistical Tolerance Limit With Expected $(1-\alpha)$ -Confidence

Theorem 7. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\ln X)$ from a sample of size n from an extreme-value distribution defined by the probability density function (8). Then an upper statistical tolerance limit with expected $(1-\alpha)$ -confidence, $U_k^\circ \equiv U_k^\circ(S)$, on future outcomes of the k th order statistic $Y_k(=\ln Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (8), which satisfies (7) is given by

$$U_k^\circ = \hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{U_k^\circ} = \ln \underline{U}_k^\circ, \quad (60)$$

where $\eta_{U_k^\circ}$ is a tolerance factor determined by

$$\eta_{U_k^\circ} = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{v(\mathbf{s}^{(r)})} \int_0^\infty \frac{w_2^{r-2} \prod_{i=1}^r \exp(s_i w_2)}{\left(\sum_{i=1}^r \exp(s_i w_2) + (n-r) \exp(s_r w_2) + [\eta_{U_k^\circ}]^{w_2} (m-l+j) \right)^r} dw_2 = \alpha \right). \quad (61)$$

Proof. The upper statistical tolerance limit with expected $(1-\alpha)$ -confidence, $U_k^\circ \equiv U_k^\circ(S)$, is obtained from a lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $L_k^\circ \equiv L_k^\circ(S)$, by replacing $1-\alpha$ by α . This completes the proof.

Theorem 8. Let $X_1 \leq \dots \leq X_r$ be the first r ordered observations of a random variable $X(=\exp X)$ from a sample of size n from a two-parameter Weibull distribution defined by the probability density function (22). Then an upper statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{U}_k^\circ \equiv \underline{U}_k^\circ(\underline{S})$, on future outcomes of the k th order statistic $Y_k(=\exp Y_k)$ from a set of m future ordered observations $Y_1 \leq \dots \leq Y_m$ also from the distribution (22), which satisfies (7) is given by

$$\underline{U}_k^\circ = \eta_{\underline{U}_k^\circ}^{1/\hat{\delta}} \hat{\beta} = \exp U_k^\circ, \quad (62)$$

where $\eta_{\underline{U}_k^\circ}$ is a tolerance factor determined by

$$\eta_{\underline{U}_k^\circ} = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{\mathfrak{g}(\mathbf{z}^{(r)})} \int_0^\infty \frac{v_2^{r-2} \prod_{i=1}^r z_i^{v_2}}{\left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} + [\eta_{\underline{U}_k^\circ}]^{v_2} (m-l+j) \right)^r} dv_2 = \alpha \right). \quad (63)$$

Proof. The upper statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{U}_k^\circ \equiv \underline{U}_k^\circ(\underline{S})$, is obtained from a lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^\circ \equiv \underline{L}_k^\circ(\underline{S})$, by replacing $1-\alpha$ by α . This completes the proof.

Inference 4 (for the tolerance factors $\eta_{\underline{U}_k^\circ}$ and $\eta_{U_k^\circ}$). It follows from (60) and (62) that

$$\eta_{\underline{U}_k^\circ} = \left(\frac{\underline{U}_k^\circ}{\hat{\beta}} \right)^{\hat{\delta}} = \left(\frac{\exp U_k^\circ}{\exp \hat{\theta}_1} \right)^{1/\hat{\theta}_2} = \exp \left(\frac{U_k^\circ - \hat{\theta}_1}{\hat{\theta}_2} \right) = \eta_{U_k^\circ}. \quad (64)$$

NUMERICAL EXAMPLES

Numerical Example 1

For the Weibull case, Lawless (1973) discusses an example with 10 items, which are put on test simultaneously; the life test is terminated at the time of the fifth failure, whence $n=10$, $r=5$, in our notation here; $\underline{X}_1=50.5$ hours, $\underline{X}_2=71.3$, $\underline{X}_3=84.6$, $\underline{X}_4=98.7$, $\underline{X}_5=103.8$; the maximum likelihood estimates of δ and β are, respectively,

$$\hat{\delta} = \left[\left(\sum_{i=1}^r \underline{x}_i^{\hat{\delta}} \ln \underline{x}_i + (n-r) \underline{x}_r^{\hat{\delta}} \ln \underline{x}_r \right) \left(\sum_{i=1}^r \underline{x}_i^{\hat{\delta}} + (n-r) \underline{x}_r^{\hat{\delta}} \right)^{-1} - \frac{1}{r} \sum_{i=1}^r \ln \underline{x}_i \right]^{-1} = 4.199, \quad (65)$$

$$\hat{\beta} = \left(r^{-1} \left(\sum_{i=1}^r \underline{x}_i^{\hat{\delta}} + (n-r) \underline{x}_r^{\hat{\delta}} \right) \right)^{1/\hat{\delta}} = 114.2796. \quad (66)$$

Based on these data, a lower 90% prediction limit (in terms of this paper, a lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, where $\alpha=0.1$) is to be constructed for the minimum of 40 independently, identically distributed lifetimes. Lawless (1973) reports a conditional lower 90% prediction limit of 8.8 hours for this example. Based on a simulation of 50 000 samples, the lower prediction limit obtained by Mee and Kushary (1994) is 8.73 hours.

Lower statistical tolerance limit with expected $(1-\alpha)$ -confidence. Taking $1-\alpha = 0.9$ and $k=1$, with $n=10$, $r=5$ and $m=40$, we have from (57) that the lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^\circ \equiv \underline{L}_k^\circ(S)$, on the minimum (Y_1) of independent lifetimes in a group of $m=40$ components which are to be put into service, is given by

$$\underline{L}_k^\circ = \eta_{\underline{L}_k^\circ}^{1/\hat{\delta}} \hat{\beta} = \exp L_k^\circ = \exp \left(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k^\circ} \right) = 8.7941146, \quad (67)$$

where, as it follows from (58) and (59), the tolerance factor $\eta_{\underline{L}_k^\circ}$ is given by

$$\eta_{\underline{L}_k^\circ} = \arg \left(\frac{1}{\mathcal{G}(\mathbf{z}^{(r)})} \int_0^\infty \frac{v_2^{r-2} \prod_{i=1}^r z_i^{v_2}}{\left(\sum_{i=1}^r z_i^{v_2} + (n-r) z_r^{v_2} + \left[\eta_{\underline{L}_k^\circ} \right]^{v_2} m \right)^r} dv_2 = 1 - \alpha \right) = \eta_{\underline{L}_k^\circ} = 2.105 / 10^5. \quad (68)$$

Statistical inference 1. It is easy to see that the conditional lower 90% prediction limit of 8.8 hours of Lawless (1973) on the minimum (Y_1) of independent lifetimes in a group of $m=40$ components, which are to be put into service, and the lower statistical tolerance limit of 8.7941146 hours with expected 0.9-confidence, which is obtained in this paper by using the proposed technique, are practically the same.

Lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence. In the above case (if $\gamma=0.9$), it follows from (43) that the lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k \equiv \underline{L}_k(S)$, on the minimum (Y_1) of independent lifetimes in a group of $m=40$ components which are to be put into service, is given by

$$\underline{L}_k = \eta_{\underline{L}_k}^{1/\hat{\delta}} \hat{\beta} = \exp L_k = \exp \left(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k} \right) = 3.7, \quad (69)$$

where, as it follows from (44) and (45), the tolerance factor $\eta_{\underline{L}_k}$ is given by

$$\eta_{L_k} = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)}{[\eta_{L_k}]^{v_2}} \frac{1}{\Gamma(r)} w^{r-1} \exp(-w) \frac{1}{g(\mathbf{z}^{(r)})} v_2^{r-2} \prod_{i=1}^r z_i^{v_2} \left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} \right)^{-r} dw dv_2 = 1 - \alpha \right) = \eta_{L_k} = 5.5451 / 10^7, \quad (70)$$

$q_{1-\gamma}=0.002631$ is a quantile of the beta distribution satisfying (38).

Statistical inference 2. Thus, the manufacturer has 90% assurance that no failures will occur in the proportion $\gamma=0.9$ or more of the population of $m=40$ components, which are to be put into service, before $L_k=3.7$ hours.

Others have computed approximate 90% prediction limits for a single future lifetime for this example. Fertig, Meyer and Mann (1980) computed a lower prediction limit of 56.98 hours, using best linear invariant estimators and a Monte Carlo estimated percentile. Engelhardt and Bain (1982) proposed two approximations; for this example they obtained 56.8 (via a procedure requiring iterative solution of a nonlinear equation) and 59.1 (via a simpler approximation). Based on a simulation of 50 000 samples, the 90% lower prediction limit obtained by Mee and Kushary (1994) for a single future observation is 56.6 hours.

Lower statistical tolerance limit with expected $(1-\alpha)$ -confidence. Taking $1-\alpha=0.9$ and $k=m=1$, with $n=10$ and $r=5$, we have from (57) that the lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^\circ \equiv \underline{L}_k^\circ(\underline{S})$, on a single future observation is given by

$$\underline{L}_k^\circ = \eta_{\underline{L}_k^\circ}^{1/\delta} \hat{\beta} = \exp L_k^\circ = \exp(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k^\circ}) = 56.641, \quad (71)$$

where, as it follows from (58) and (59), the tolerance factor $\eta_{\underline{L}_k^\circ}$ is given by

$$\eta_{\underline{L}_k^\circ} = \arg \left(\frac{1}{g(\mathbf{z}^{(r)})} \int_0^\infty \frac{v_2^{r-2} \prod_{i=1}^r z_i^{v_2}}{\left(\sum_{i=1}^r z_i^{v_2} + (n-r)z_r^{v_2} + [\eta_{\underline{L}_k^\circ}]^{v_2} \right)^r} dv_2 = 1 - \alpha \right) = \eta_{\underline{L}_k^\circ} = 0.052479. \quad (72)$$

Statistical inference 3. Based on a simulation of 50 000 samples, the 90% lower prediction limit obtained by Mee and Kushary (1994) for a single future lifetime is 56.6 hours, which is slightly smaller than 56.641 hours (see (71)). Engelhardt and Bain (1982) proposed the first approximate lower prediction limit of 56.8 hours and Fertig, Meyer and Mann (1980) computed the lower prediction limit of 56.98 hours for a single future lifetime, which are slightly larger than 56.641 hours (see (71)). The second approximate lower prediction limit of 59.1 hours proposed by Engelhardt and Bain (1982) for a single future lifetime is larger than 56.641 hours (see (71)).

Numerical Example 2

Consider the following results given by Lieblein and Zelen (1956) of test of endurance, in millions of revolutions, of $n=23$ ball bearings: 17.88, 28.92, 33.00, 41.52, 42.12, 45.60, 48.48, 51.84, 51.96, 54.12, 55.56, 67.80, 68.64, 68.64, 68.88, 84.12, 93.12, 98.64, 105.12, 105.84, 127.92, 128.04, 173.40. The maximum likelihood estimates of δ and β are, respectively,

$$\hat{\delta} = \left[\left(\sum_{i=1}^n x_i^{\hat{\delta}} \ln x_i \right) \left(\sum_{i=1}^n x_i^{\hat{\delta}} \right)^{-1} - \frac{1}{n} \sum_{i=1}^n \ln x_i \right]^{-1} = 2.102, \quad (73)$$

$$\hat{\beta} = \left(n^{-1} \left(\sum_{i=1}^n x_i^{\hat{\delta}} \right) \right)^{1/\hat{\delta}} = 81.878. \quad (74)$$

Numerous authors have used these data as illustrative of a sample from a two-parameter Weibull distribution. Using 20 000 simulated samples of size $n=23$, Mee and Kushary (1994) obtained a 90% lower prediction limit for the fifth failure out one hundred ball bearings equal to 10.11 million of revolutions, which is slightly smaller than the two approximate prediction limits 10.27 and 10.59 reported by Engelhardt and Bain (1982).

Lower statistical tolerance limit with expected $(1-\alpha)$ -confidence. Taking $1-\alpha = 0.9$ and $k=5$, with $r=n=23$ and $m=100$, we have from (57) that the lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^{\circ} \equiv \underline{L}_k^{\circ}(\underline{S})$, for a fifth failure out one hundred ball bearings is given by

$$\underline{L}_k^{\circ} = \eta_{\underline{L}_k^{\circ}}^{1/\hat{\delta}} \hat{\beta} = \exp L_k^{\circ} = \exp \left(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k^{\circ}} \right) = 10.35206, \quad (75)$$

where, as it follows from (58) and (59), the tolerance factor $\eta_{\underline{L}_k^{\circ}}$ is given by

$$\eta_{\underline{L}_k^{\circ}} = \arg \left(\sum_{l=0}^{k-1} \binom{m}{l} \sum_{j=0}^l \binom{l}{j} (-1)^j \frac{1}{\mathfrak{g}(\mathbf{z}^{(n)})} \int_0^{\infty} \frac{v_2^{n-2} \prod_{i=1}^n z_i^{v_2}}{\left(\sum_{i=1}^n z_i^{v_2} + [\eta_{\underline{L}_k^{\circ}}]^{v_2} (m-l+j) \right)^n} dv_2 = 1-\alpha \right) = \eta_{\underline{L}_k^{\circ}} = 0.0129452. \quad (76)$$

Statistical inference 4. Thus, it follows from (75) that the lower statistical tolerance limit with expected confidence of 0.9 ($\underline{L}_k^{\circ} = 10.35206$ million of revolutions) is between the two approximate prediction limits 10.27 and 10.59 reported by Engelhardt and Bain (1982).

Lower statistical tolerance limit with expected $(1-\alpha)$ -confidence. Taking $1-\alpha = 0.9$ and $k=1$, with $r=n=23$ and $m=100$, we have from (57) that the lower statistical tolerance limit with expected $(1-\alpha)$ -confidence, $\underline{L}_k^{\circ} \equiv \underline{L}_k^{\circ}(\underline{S})$, for a first failure out one hundred ball bearings, is given by

$$\underline{L}_k^\circ = \eta_{\underline{L}_k^\circ}^{1/\hat{\delta}} \hat{\beta} = \exp L_k^\circ = \exp(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k^\circ}) = 2.083, \quad (77)$$

where, as it follows from (58) and (59), the tolerance factor $\eta_{\underline{L}_k^\circ}$ is given by

$$\eta_{\underline{L}_k^\circ} = \arg \left(\frac{1}{g(\mathbf{z}^{(n)})} \int_0^\infty \frac{v_2^{n-2} \prod_{i=1}^n z_i^{v_2}}{\left(\sum_{i=1}^n z_i^{v_2} + [\eta_{\underline{L}_k^\circ}]^{v_2} \right)^n} dv_2 = 1 - \alpha \right) = \eta_{\underline{L}_k^\circ} = 0.00044503. \quad (78)$$

Statistical inference 5. Lawless (1973) obtained for this example (via conditional approach in terms of a extreme-value (Gumbel) distribution) the lower 90% prediction limit of 2.08 million of revolutions for a first failure out one hundred ball bearings, which is slightly smaller than 2.083 (see (77)).

Numerical Example 3

Consider the data in an example discussed by Mann and Saunders (1969). They regard the data coming from the Weibull distribution as the results of full scale fatigue tests on a particular type of component. The data are for a complete sample of size $n=3$, with observations $X_1=45.952$, $X_2=54.143$, and $X_3=65.440$, results being expressed here in number of thousands of cycles. On the basis of these data it is wished to obtain the lower statistical tolerance limit with expected $(1-\alpha)$ -confidence for the minimum (Y_1) of independent lifetimes in a group of $m=500$ components which are to be put into service.

Lower statistical tolerance limit with expected $(1-\alpha)$ confidence. The maximum likelihood estimates of the unknown parameters δ and β , computed on the basis of (X_1, X_2, X_3) , are $\hat{\delta} = 7.726$ and $\hat{\beta} = 58.706$, respectively. Taking $1-\alpha = 0.8$ and $k=1$, with $r=n=3$ and $m=500$, we have from (57) that the lower statistical tolerance limit with expected $(1-\alpha)$ confidence, $\underline{L}_k^\circ \equiv \underline{L}_k^\circ(\underline{S})$, on the minimum (Y_1) of independent lifetimes in a group of $m=500$ components which are to be put into service, is given by

$$\underline{L}_k^\circ = \eta_{\underline{L}_k^\circ}^{1/\hat{\delta}} \hat{\beta} = \exp L_k^\circ = \exp(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k^\circ}) = 5.527411, \quad (79)$$

where, as it follows from (58) and (59), the tolerance factor $\eta_{\underline{L}_k^\circ}$ is given by

$$\eta_{\underline{L}_k^\circ} = \arg \left(\frac{1}{g(\mathbf{z}^{(n)})} \int_0^\infty \frac{v_2^{n-2} \prod_{i=1}^n z_i^{v_2}}{\left(\sum_{i=1}^n z_i^{v_2} + [\eta_{\underline{L}_k^\circ}]^{v_2} \right)^n} dv_2 = 1 - \alpha \right) = \eta_{\underline{L}_k^\circ} = 1.18 / 10^8. \quad (80)$$

Statistical inference 6. Lawless (1973) obtained for this example (via conditional approach in terms of the extreme-value (Gumbel) distribution) the lower 80% prediction limit of 5.623, which is slightly larger than 5.527411 (see (79)). The resulting lower 80% prediction limit of Mee and Kushary (1994) for this example (obtained via simulation of 100 000 samples) was 5.225, which is slightly smaller than

5.527411 (see (79)). The Mann and Saunders (1969) result for this example was only 0.766. All results are expressed here in the number of thousands of cycles.

Lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence. Taking $\gamma=0.8$, $1-\alpha=0.8$ and $k=1$, with $r=n=3$ and $m=500$, we have from (43) that a lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence, $L_k \equiv L_k(\mathcal{S})$, on the minimum (Y_1) of independent lifetimes in a group of $m=500$ components which are to be put into service, is

$$\underline{L}_k = \eta_{\underline{L}_k}^{1/\delta} \hat{\beta} = \exp L_k = \exp(\hat{\theta}_1 + \hat{\theta}_2 \ln \eta_{\underline{L}_k}) = 4.082282, \quad (81)$$

where, as it follows from (44) and (45), the tolerance factor $\eta_{\underline{L}_k}$ is given by

$$\eta_{\underline{L}_k} = \arg \left(\int_0^\infty \int_0^\infty \frac{\ln(1-q_{1-\gamma})^{-1} \sum_{i=1}^n Z_i^{v_2}}{[\eta_{\underline{L}_k}]^{v_2}} \frac{1}{\Gamma(n)} w^{n-1} \exp(-w) \frac{1}{g(\mathbf{z}^{(n)})} v_2^{n-2} \prod_{i=1}^n z_i^{v_2} \left(\sum_{i=1}^n z_i^{v_2} \right)^{-n} dw dv_2 = 1 - \alpha \right) = \eta_{\underline{L}_k} \\ = 1.135/10^9, \quad (82)$$

$q_{1-\gamma}$ is a quantile of the beta distribution satisfying (38).

Statistical inference 7. Thus, the manufacturer has 80% assurance that no failures will occur in the proportion $\gamma=0.8$ or more of the population of $m=500$ components, which are to be put into service, before $\underline{L}_k=4.082282$ thousands of cycles.

FUTURE RESEARCH DIRECTIONS

Predictive inferences (via tolerance limits) for future outcomes on the basis of the past and present knowledge represent a fundamental problem of statistics, arising in many contexts and producing varied solutions. In this article, new-sample prediction (via tolerance limits) based on a previous sample is considered (i.e., when for predicting the future outcomes in a new sample there are available the observed data only from a previous sample). It is interesting to consider within-sample prediction (via tolerance limits) based on the early data from a current experiment (i.e., when for predicting the future outcomes in a sample there are available the early data only from that sample), and new-within-sample prediction (via tolerance limits) based on both the early data from that sample and the data from a previous sample (i.e., when for predicting the future outcomes in a new sample there are available both the early data from that sample and the data from a previous sample), where it is assumed that only the functional form of the underlying distributions is specified, but some or all of its parameters are unspecified.

Applications of Exact Statistical Tolerance Limits on Future Random Quantities for Prognostics and Health Management of Complex Systems

Prognostics and Health Management (PHM) is a set of means, approaches, methods and tools that allows monitoring and tracking the health state of a system in order to detect, diagnose and predict its failures. Topics of interest include, but are not limited to:

- (1) Prognostics and Health Management in Cyber-Physical Systems;
- (2) Fault detection, diagnostics and prognostics (data-driven, model-based and hybrid methods);
- (3) Remaining Useful Life (RUL) computation and prediction;
- (4) Post-diagnostics and post-prognostics decision;
- (5) Condition monitoring and sensors placement and optimization;
- (6) Feature extraction and selection, Health Indicators construction;
- (7) Modelling and simulation of interdependent failure mechanisms;
- (8) Advanced computation and simulation methods;
- (9) Industrial applications.

Prognostics and Health Management (PHM) aims at development and publishing original scientific contributions and industrial applications dealing with the topics covered by PHM in the areas of condition monitoring, fault detection, fault diagnostics, fault prognostics and decision support. The results obtained are then exploited to take appropriate decisions to increase the system's availability, reliability and security while reducing its maintenance costs.

Development of Novel Technologies of Prognostics and Health Management (PHM) for l -out-of- m Systems on the Basis of the Exact Statistical Tolerance Limits

Many technical systems or subsystems have l -out-of- m structure. These so-called l -out of- m systems consist of m components of the same kind. The entire system is working if at least l of its m components are operating. It fails if $m - l + 1$ or more components fail. Hence, a l -out-of- m system breaks down at the time of the $(m - l + 1)$ th component failure. Since all components start working at the same time, this approach leads to a kind of redundancy called active redundancy of $m - l$ components. Important particular cases of l -out-of- m systems are parallel and series systems corresponding to $l = 1$ and $l = m$, respectively. Practical examples of l -out-of- m systems are, e.g., an aircraft with four engines which will not crash if at least two out of its four engines remain functioning, or a satellite which will have enough power to send signals if not more than four out of its ten batteries are discharged.

Prediction problems come up naturally in several real life situations. For example, they can be broadly classified under two categories: (i) the variable to be predicted comes from the same experiment or sample so that it may be correlated with the observed data, (ii) it comes from an independent future experiment. Both of these situations do arise in the context of reliability and lifetesting. Formally the problems in the first category are known as one-sample (or within-sample) problems and those in the latter constitute two-sample (or new-sample) problems as well as multi-sample problems.

Suppose a system consists of m components and fails whenever l of these components fail. Such a system is referred to as l -out-of- m system. Suppose our observations consist of the first k failure times, and the goal is to predict the failure time of the system. Assuming that the components' life lengths are identically and independently distributed, we have a prediction problem involving a Type II censored sample, and it falls into category (i). Formally, the problem is to predict Y_l having observed $(Y_1 \leq \dots \leq Y_k)$, $k < l$. A popular choice for the lifelength of the components is the exponential distribution. Thus, one can think of a point predictor or an interval predictor for the lifelength of the system as one-sample (or within-sample) problem.

Consider the third situation where a manufacturer of certain equipment is interested in setting up a warranty for the equipment in a lot being sent out to the market. Using the information based on a small

sample, possibly censored, the goal is to predict and set a lower prediction limit for the weakest item in a future sample. Typical assumption here is that the two samples are independent. This falls into category (ii), and we call it a two-sample (or new-sample) problem. One may be interested in the lifelength of the l -th weakest item and the average lifelength simultaneously. Then our focus will be on a prediction region for the two variables of interest.

While several researches have concentrated on the above problems there are some papers dealing with special prediction situations involving several independent random samples. These belong to category (ii) and can be taken into account.

In reliability theory, the lifetime of a l -out-of- m system is usually described by the $(m - l + 1)$ th order statistic Y_{m-l+1} from the sample $Y_1 \leq \dots \leq Y_m$, where the random variable Y_i represents the lifetime or failure time of the i th component of the system, $1 \leq i \leq m$. In the conventional modelling of these structures, the component lifetimes are supposed to be independent and identically distributed random variables. *Translating this approach back into the technical sphere, it reflects the assumption that the failure of any component does not affect the remaining ones. However, the supposition that the breakdown of some component will have no impact on the system parts at work will generally not be fulfilled in practice. In some systems, a component failure will more or less strongly influence the remaining parts of the system. For example, the breakdown of an aircraft's engine will increase the load put on the remaining engines such their lifetimes tend to be shorter. Thus, a more flexible model, which is therefore more applicable to practical situations, must take some dependence among the system components into account.*

Prognostics and Health Management (PHM) offers several benefits for predictive maintenance. It predicts the future behavior of l -out-of- m system as well as its Remaining Useful Life (RUL). This RUL is used to plan the maintenance operation to avoid the failure, the stop time and optimize the cost of the maintenance and failure. However, with the development of the industry the assets are nowadays distributed, this is why the PHM needs to be developed using the new Information Technologies. In this paper, we propose a PHM solution based on the exact statistical prediction and tolerance limits on future random quantities (for example, future order statistics coming from Log-Location-Scale Distributions). These statistical limits will be constructed via the Pivotal Quantity Averaging Approach (PQAA), which represents the conceptually simple, efficient and useful method for constructing exact statistical prediction and tolerance limits on future outcomes under parametric uncertainty of underlying models. Nechval et al. (2014b, 2014c) discuss some of the problems described in this section.

Development of Novel Technologies of Prognostics and Health Management (PHM) for Fatigued Structures on the Basis of the Exact Statistical Tolerance Limits

From an engineering standpoint the fatigue life of a fatigued structure consists of two periods: (i) crack initiation period, which starts with the first load cycle and ends when a technically detectable crack is presented, and (ii) crack propagation period, which starts with a technically detectable crack and ends when the remaining cross section can no longer withstand the loads applied and fails statically. The main aim of this paper is to present more accurate innovative stochastic fatigue model for adaptive planning inspections of fatigued structures in damage tolerance situations via observations of crack growth process during a crack propagation period. A new crack growth equation is based on this model. It is attractively simple and easy to apply in practice for effective in-service inspection planning (with decreasing intervals between sequential inspections as alternative to constant intervals often used in practice for convenience in operation). During the period of crack propagation (when the damage tolerance situation is used), the

proposed crack growth equation, based on the innovative model, allows one to construct more accurate and effective reliability-based inspection strategy in this case.

Prognostics and Health Management (PHM) is a technology to enhance the effective reliability and availability of a fatigued structure in its life cycle conditions by detection of current and approaching failures and by providing for mitigation of the structure risks. Prognostics is the real-time enhancement of reliability and availability and the prediction of the remaining useful life of the structure by assessing the extent of deviation or degradation of the monitored parameters of the structure from its expected normal operating conditions. Prognostics can yield an advance warning of impending failure in a structure, thereby enabling more efficient and effective maintenance and corrective actions. Prognostics help in preventing catastrophic failures and can reduce unscheduled maintenance expenses. The outputs of a prognostic assessment of a structure are the failure risk, time to failure, remaining useful life, and a prognostic distance within which maintenance and repair actions can be planned, in order to minimize their impact on system availability. Health Management is the process of using diagnostic and prognostic information to intelligently manage the use and maintenance of a system. The ultimate result is increased effective reliability, availability, and safety with reduced logistics and support costs.

Prognostics and Health Management (PHM) can be used to solve the service problems of the following important engineering structures: (1) Transportation Systems and Vehicles – aircraft, space vehicles, trains, ships; (2) Civil Structures – bridges, dams, tunnels; (3) Power Generation – nuclear, fossil fuel and hydroelectric plants; (4) High-Value Manufactured Products – launch systems, satellites, semiconductor and electronic equipment; (5) Industrial Equipment – oil and gas exploration, production and processing equipment, chemical process facilities, pulp and paper. . Nechval et al. (2015, 2018b) discuss some of the problems described in this section.

Development of Novel Technologies of Prognostics and Health Management (PHM) for a New Product in Systems of Lifetime Testing on the Basis of the Exact Statistical Tolerance Limits

A new product lifetime testing represents the problem that can be stated as follows. A new product is submitted for lifetime testing. The product will be accepted if a random sample of n items shows r or fewer failures in performance testing. We want to know whether to stop the test before it is completed if the results of the early observations are unfavourable. A suitable stopping decision saves the cost of the waiting time for completion. On the other hand, an incorrect stopping decision causes an unnecessary design change and a complete rerun of the test. It is assumed that the redesign would improve the product to such an extent that it would definitely be accepted in a new lifetime testing. The paper presents a stopping rule based on the statistical estimation of total costs involved in the decision to continue beyond an early failure. Sampling is both expensive and time consuming. Hence, there are situations where it is more efficient to take samples sequentially, as opposed to all at one time, and to define a stopping rule to terminate the sampling process.

At the planning stage of a statistical investigation the question of sample size (n) is critical. For such an important issue, there is a surprisingly small amount of published literature. Engineers who conduct reliability tests need to choose the sample size when designing a test plan. The model parameters and quantiles are the typical quantities of interest. The large-sample procedure relies on the property that the distribution of the t -like quantities is close to the standard normal in large samples. To estimate these quantities the maximum likelihood method is often used. The large-sample procedure to obtain the sample size relies on the property that the distribution of the above quantities is close to standard

normal in large samples. The normal approximation is only first order accurate in general. When sample size is not large enough or when there is censoring, the normal approximation is not an accurate way to obtain the confidence intervals. Thus sample size determined by such procedure is dubious. Therefore, it may be considered the problem of constructing a test which minimizes the maximum expected sample size under some constraints. Stopping rules in sample testing can save substantial time and resources, when the case is clear-cut.

Prognostics and Health Management (PHM) is essential in guaranteeing the safe, efficient, and correct operation of complex of detection, isolation and identification of faults; and prognosis, which consists of prediction of the remaining useful life (RUL) of components, subsystems, or systems, constitutes system health monitoring. PHM aims to provide users with an integrated view of the health state of equipment or overall system. Nechval et al. (2009) discusses some of the problems described in this section.

CONCLUSION

In this article, we construct the following one-sided statistical tolerance limits: i) one-sided statistical tolerance limit that covers at least $100\gamma\%$ of the measurements with expected $100(1-\alpha)\%$ confidence, ii) one-sided statistical tolerance limit determined so that the expected proportion of the measurements covered by this limit is $(1-\alpha)$. Tolerance limits have important role in application of statistical methods in technical practice, especially in statistical quality control. Inherent in every phase of industrial quality control is the problem of comparing some quality characteristic or measurement of a finished product against given specifications. Sometimes the specifications, or *tolerance limits*, are so stated by the customer or by design engineer that any appreciable departure will make the product unusable. There remains, however, the problem of producing the part so that an acceptably high proportion of units will fall within tolerance limits specified for the given quality characteristic. Also, if a product is made without prior specifications, or if modifications are made, it is desirable to know within what limits the process can hold a quality characteristics a reasonably high percentage of the time. We thus speak of natural tolerance limits; that is, we let the process establish its own limits which, according the experience, can be met in actual practice.

The new analytical technique proposed in this article represents the conceptually simple, efficient and useful method for constructing exact statistical tolerance limits on future outcomes under parametric uncertainty of underlying models. It does not in need to make any assumption concerning the statistical equation for the tolerance limit. This technique, using the experimental complete or type II censored data, is based on the idea of invariant embedding of a sample statistic in the underlying model to construct pivotal quantities and to eliminate the unknown parameters from the problem via pivotal quantity averaging. In this case, the exact statistical tolerance limits (under parametric uncertainty of underlying models) on future outcomes (say, order statistics) associated with sampling from corresponding distributions can be found easily and quickly making tables, simulation and special computer programs unnecessary.

The analytical methodology described in this paper is illustrated for the two-parameter Weibull and extreme-value distributions. Applications to other log-location-scale distributions could follow directly.

Finally, we give the three illustrative numerical examples, where the exact statistical tolerance limits with expected $(1-\alpha)$ -confidence, obtained in this paper in terms of the two-parameter Weibull or extreme-value distribution, are compared with the known results that are reported in the literature and were obtained by using the following: 1) tables, 2) simulation, 3) Monte Carlo estimated percentiles, 4)

special computer programs, 5) approximation, 6) transformation of the two-parameter Weibull distribution to the extreme-value distribution, etc.

Although the details of the problems addressed in the article can vary significantly from one industry to another, the focus is always on making more accurate decisions, rather than manually using guesses and intuitions, but rather from a scientific point of view using models and technologies implemented with disciplined processes and systems.

The methodologies described here can be extended in several different directions to solve various problems arising in practice.

KEY TERMS AND DEFINITIONS

Extreme-Value Distribution: The so-called first asymptotic distribution of extreme values, hereafter referred to simply as the extreme-value distribution, which is extensively used in a number of areas as a lifetime distribution and sometimes referred to as the Gumbel distribution.

Future Outcome: The value of the k th order statistic, $1 \leq k \leq m$, in a future random sample of m ordered observations $Y_1 \leq \dots \leq Y_m$.

Parametric Uncertainty: It is assumed that only the functional form of the underlying distributions is specified, but some or all of its parameters are unspecified. In this article, it is assumed that both parameters of the underlying distributions are unknown.

Statistical γ -Content Tolerance Limit with Expected $(1-\alpha)$ -Confidence: An upper statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence is determined so that with the given expected confidence level $1-\alpha$, a specified proportion γ or more of the population will fall below the limit. A lower statistical γ -content tolerance limit with expected $(1-\alpha)$ -confidence satisfies similar conditions.

Statistical Tolerance Limit with Expected $(1-\alpha)$ -Confidence: An upper statistical tolerance limit with expected $(1-\alpha)$ -confidence is determined so that the expected proportion of the population failing below the limit is $(1-\alpha)$. A lower statistical tolerance limit with expected $(1-\alpha)$ -confidence satisfies similar conditions.

Two-Parameter Weibull Distribution: This two-parameter distribution is one of the most widely used life distributions in reliability analysis. It is very flexible, and can, through an appropriate choice of parameters, model many types of failure rate behaviors. The distribution has wide applications in diverse disciplines.

Type II Censored Data: In this case, we only observe, say, the r smallest observations in a random sample of n items.

The Structure of DNA Taking Into Account the Higher Dimension of Its Components

Skolkovo, Russia

INTRODUCTION

Deoxyribonucleic acid (DNA), as a chemical substance, it was isolated by Johann Friedrich Misher in 1869 from the remains of cells contained in the pus. He singled out a substance that includes nitrogen and phosphorus. When Misher determined that this substance has acid properties, the substance was called nucleic acid (Dahm, 2005). Gradually it was proved that it was DNA, and not proteins, as previously thought, and which is the carrier of genetic information. One of the first decisive proofs was the experiments of Oswald Avery, Colin MacLeod and McLean McCarthy (1944) on the transformation of bacteria.

The structure of the double helix DNA it was proposed by Francis Crick and James Watson in 1953 on the base of the X-ray structural data obtained by Maurice Wilkins and Rosalind Franklin and the “Chargaff rules” according to which in each DNA molecule the strict relationships connecting the quantity of nitrogenous bases of different (Watson, & Crick, 1953a, b). For outstanding contributions to this discovery, Francis Crick, James Watson and Maurice Wilkins were awarded the 1962 Nobel Prize in Physiology or Medicine. Deoxyribonucleic acid (DNA) is a biopolymer, the monomer of which is the nucleotide (Albert, et al., 2002; Butler, 2005). Each nucleotide consists of a phosphoric acid residue attached to sugar deoxyribose, to which one of the four nitrogen bases is attached also. The bases that make up the nucleotides are divided into two groups: purines (adenine [A] and guanine [G]) and pyrimidines (cytosine [C] and thymine [T]) are formed by combined five - and six - membered heterocycles.

They managed to show that the DNA isolated from the pneumococci corresponds to the so-called transformation (the acquisition of pathogenic properties by a harmless culture as result of the addition of dead pathogenic bacteria to it). The experiment of American scientists Alfred Hershey and Martha Chase (Hershey - Chase experiment, 1952) with radioactively labeled proteins and bacteriophage DNA showed that only the phage nucleic acid is transmitted to the infected cell, and the new generation of phage contains the same proteins and nucleic acid, as the initial phage (Hershey & Chase, 1952). Deciphering the structure of DNA (1953) has become one of the turning points in the history of biology.

In 1986, Frank-Kamenetskiy in Moscow showed how a double-stranded DNA folds into a so-called H - shape, composed not of two but three strands of DNA (Frank – Kamenetskiy, 1986, 1988). Deoxyribonucleic acid (DNA) is a biopolymer, the monomer of which is the nucleotide (Albert et al., 2002; Butler, 2005).

Nucleotides are long polynucleotide chains covalently linked. These chains in the overwhelming majority of cases (except for some viruses possessing single - stranded DNA genomes) are combined pairwise by means of hydrogen bonds into a secondary structure, called the double helix (Watson & Crick, 1953 a, b; Berg, Tymoczko & Stryer, 2002). Each base on one of the chains is connected to one definite base on the second chain. This specific binding is called complementary. Purines are complementary to pyrimidines (that is, they are capable of forming hydrogen bonds with them): adenine forms bonds

DOI: 10.4018/978-1-7998-3479-3.ch050

only with thymine, and cytosine - with guanine. In a double helix, chains are also linked by hydrophobic interactions and stacking, which do not depend on the DNA base sequence (Ponnuswamy & Gromiha, 1994). Complementarity of the double helix means that the information contained in one chain is also contained in another chain. Different base pairs form a different number of hydrogen bonds. In the future, the existence of nucleic acids differing in the length of the period and shape with rotation of the spiral both to the right and to the left was experimentally established (Ha, et al., 2005; Cantor, & Schimmel, 1980; Frank – Kamenetskiy, 2010).

Watson and Crick postulated the spiral form of the DNA molecule, but they did not discuss the reasons for the formation of such a DNA molecule. Until now there have been no works explaining the existence of a spiral in the DNA molecule.

In the book (Zhizhin, 2017), the molecules of practically all the elements of the periodic system were studied in detail and it was shown that many of them, including magnesium and calcium, form compounds of higher dimension (see also Zhizhin, 2015 a, b; Zhizhin, & Diudea, 2016; Zhizhin, Khalaj, & Diudea, 2016). In the works (Zhizhin, 2016 a, b), the structures of biomolecules, which also form compounds of higher dimension, are also studied. When analyzing the metric space of nucleic acid structures, one should use the representations of their constituents in the form of polytopes of higher dimension. This primarily applies to the phosphoric acid residues and the *D* - ribose molecules, since nitrogenous bases have a dimensionality of 2 and do not have a significant effect on the geometric structure of nucleic acids.

The determination of the geometric forms of chemical compounds according to the Euler-Poincaré (Poincare, 1895) relation translates classical stereochemistry in three-dimensional space into sulfur chemistry in a space of higher dimension. Here new discoveries are possible in the laws of chemical compounds. Consideration of the geometry of molecules using spaces of higher dimension makes it possible to explain the facts observed in reality, which previously had no clear explanations. In the book (Zhizhin, 2017), for example, showed that the rotation of the plane of light polarization in tartaric acid is due to the difference in the shapes of the molecules of *D* - tartaric acid and *L* - tartaric acid, which is clearly visible in their images in five - dimensional space, since their dimension is five. Pasteur (Pasteur, 1960) also tried to explain the rotation of the polarization plane of light in liquid tartaric acid by the difference in the structures of the crystals of *D* - tartaric acid and *L* - tartaric acid. This book received an explanation for the fact that there is no branching in the chain of glucose molecules, if they are bound in β - glycoside linkage. If these molecules are bound in α - glucoside linkage, branching of the chain is possible. It is shown that, because of the higher dimensionality of glucose molecules in the case of a β - glycoside linkage, the centers of possible branching of the chain are blocked by glucose molecules. In this time, with α - glycoside linkage the possible branching points of the chain remain free.

The concept of the geometric correspondence of the structure of substances in the formation of a chemical compound is essential for the form of the compound. However, the complementarity of DNA spirals when connecting spirals can not be the reason for the formation of these spirals. The geometric shape of the constituent parts of the spiral itself must be important here. They are phosphoric acid residues and *D* - ribose molecules. This paper is devoted to the investigation of this problem. In this case it is necessary to take into account the dimension of these parts, which, as shown in (Zhizhin, 2017), is higher than three. It should be noted, that there is no contradiction in the representation of the structure of DNA as a spiral in a three - dimensional space with the highest dimension of its components. The point is that according to the geometry of Riemann (Riemann, 1854), a space of higher dimension has a boundary. Therefore, a space of a smaller dimension can be located outside this space.

The higher dimensionality of molecules can be considered as an example of Big Data. The concept of Big Data has become widespread in computer science in recent times (Kosrapohr, 2003; Hughes,

2011). The representation of molecules in the form of polytopes of higher dimension means the handling of Big Data as geometric images of a set of points in a space of higher dimension. A striking example of the use of the concept of Big Data in medicine is a work of J.A. Rodger (Rodger, 2015) in which, using the intellectual analysis of Big Data, a program has been developed to improve the prognosis of survival rates for traumatic brain injury and other injuries on several ships. The totality of injury data for each vessel can be considered as Big Data in view of the many parameters characterizing trauma.

THE DIMENSION OF PHOSPHORIC ACID AND ITS RESIDUE

The phosphoric acid H_3PO_4 has the following building (see, for example, Karapetians & Drakin, 1994) (Figure 1).

Figure 1. Special structure of phosphoric acid

On the Figure 2 is presented Fisher's formula of phosphoric acid.

Figure 2. Fisher's formula of phosphoric acid

It is obvious that, used in the DNA molecule, the phosphoric acid residue obtained by detaching one hydrogen atom from it has the building also. In this case, instead of one of the hydroxyl groups attached to the phosphorus atom, there will be a negatively charged oxygen atom. To determine the functional topological dimension of phosphoric acid and its residue, it is necessary to connect the vertices, atoms and functional groups entering into these compounds (Zhizhin, 2016b, 2017). Then the structure of phosphoric acid and its residue is represented in the form of a polytope in Figure 3.

Figure 3. The polytope of the phosphoric acid and its residue

In Figure 3 in vertices a dispose atom phosphoric; in vertices c dispose atom of oxygen with double bond; in vertices b, d, e dispose atoms of oxygen with free bond.

Calculation of the functional topological dimension by the Euler-Poincaré equation (Poincaré, 1895) does not require specifying the exact lengths of polytope edges, and for a given number of the vertices does not depend on the groups of atoms in these vertices (Zhizhin, 2016b). In Figure 3, the edges corresponding to the covalent chemical bonds are marked in red, and the edges that carry only the geometric function, delineating the closed geometric figure, are marked in blue.

It follows from Figure 3 that the polytope of phosphoric acid has five vertices (a, b, c, d, e), ten edges ($ac, ab, ad, ae, cd, de, be, ce, cb, bd$), ten plane triangular faces ($cbe, cda, cea, dab, db e, dce, bae, dae, bce, dcb$), and five three - dimensional faces in the form of tetrahedron ($cbae, caed, cbad, abde, cebd$). These values of elements of different dimensions we must substitute into the Euler - Poincare equation

$$\sum_{i=0}^{n-1} f_i (-1)^i = 1 - (-1)^n, \quad (1)$$

where f_i is the number of elements with dimension i in polytope with dimension n . In this case there are $f_0=5, f_1=10, f_2=10, f_3=5$.

Substituting these values into equation (1), can to obtain

$$5 - 10 + 10 - 5 = 0.$$

Thus, equation (1) is satisfied for $n = 4$. This proves that the polytope of phosphoric acid and its residue has a dimension of four. It is worth emphasizing that the polytope of phosphoric acid and its residue is topologically equivalent to a convex polytope of the simplex type with dimension four, since these polytopes completely coincide with the values of the numbers of elements of different dimensions (Zhizhin, 2014b). The origin of the four - dimensional space can be placed in one of the vertices with sending coordinates along the edges connecting this vertex to other vertices (see Figure 3).

THE DIMENSION OF THE DEOXYRIBOSE

The deoxyribose (or the *D* – ribose) is molecule of carbohydrate with five atoms carbon. There are two enantiomer forms of this molecule. Its images in the form of Fisher's formula (Metzler, 1980) are shown in Figure 4 A, B.

Figure 4. A, B. Two enantiomer forms of the molecule *D* – ribose (formulas of Fisher's)

In the DNA molecule, *D* - ribose as a component enters with a closed carbon chain. The closed chain of the molecule in Figure 4 is formed due to the rupture of the double bond between oxygen and carbon (considering it the first in the chain), the liberation of the water molecule, and the addition of this oxygen atom to the penultimate (fourth) carbon atom in the carbon chain. The Fischer formula or formula Haworth and their modifications (Metzler, 1980; Lehninger, 1982) may not reflect the spatial structure of the *D* – ribose molecule. For this target the constructs described in the form of convex polytopes with boundary elements which form boundary complex (Grunbaum, 1967). Only when such a representation will be to determine the dimension of these molecules (Zhizhin, 2016 b; 2017). Figure 5 shows the result of the closure of a chain of four carbon atoms through an oxygen atom correspondent Figure 4 A. Chemical bonds are marked as before with red color.

It is easy to see that, in addition to the form of the *D* - ribose molecule in Figure 5 (a form of A), there is another enantiomer form of this molecule. It connected by a symmetry transformation with respect to a straight line passing through an oxygen atom separating the projection of the form of A in half (we shall assume that it is a B shape). Form B of the *D* - ribose molecule is shown in Figure 6.

In order to give the *D* - ribose molecule a kind of polytope, it is necessary to connect each vertex (every atom or functional group, with all other vertices) to the ribs, then can to get a polytope of the simplex type, the dimension of which must be determined.

Figure 5. The molecule *D* – ribose with closed a chain of carbon atoms (the form A)

Figure 6. The molecule *D* – ribose with closed a chain of carbon atoms (the form B)

Figure 7 shows an image of a *D* - ribose molecule (A) with a closed carbon chain in the form of a polytope.

Figure 7. The molecule *D* – ribose (A) in form of the polytope

In contrast to the previous works of the author (Zhizhin, 2016 b; 2017), all hydroxyl groups are transferred to the periphery of the image of the molecule. This is more convenient for considering possible chemical reactions of *D* - ribose with other compounds.

The polytope at Figure 7 has 13 vertices in which there are one oxygen atom, four hydrogen atoms, three hydroxyl groups, four carbon atoms, compound CH_2OH . It is known that the dimension of a simplex is one less than the number of its vertices (Grünbaum, 1967). Therefore, the dimension of the polytope in Figure 7, if the Euler - Poincaré equation (1) holds for it, equals $n=f_0 - 1=12$. The simplex is a simplicial polytope, and all its faces therefore are simplexes. Since all the vertices of a simplex are related to each other, the number of edges is determined by the number of combinations of the number of vertices of two. In this case, the number of edges of the polytope in Figure 7 is $f_1 = C_{n+1}^2 = 78$.

The number of two - dimensional faces (triangles) of this polytope is $f_2 = C_{n+1}^3 = 286$.

The number of three - dimensional faces (tetrahedrons) of this polytope is $f_3 = C_{n+1}^4 = 715$.

The number of four - dimensional faces (4 - simplexes) of this polytope is $f_4 = C_{n+1}^5 = 1287$.

The number of five - dimensional faces (5 - simplexes) of this polytope is $f_5 = C_{n+1}^6 = 1716$.

The number of six - dimensional faces (6 - simplexes) of this polytope is $f_6 = C_{n+1}^7 = 1716$.

The number of seven - dimensional faces (7 - simplexes) of this polytope is $f_7 = C_{n+1}^8 = 1287$.

The number of eight - dimensional faces (8 - simplexes) of this polytope is $f_8 = C_{n+1}^9 = 715$.

The number of nine - dimensional faces (9 - simplexes) of this polytope is $f_9 = C_{n+1}^{10} = 286$.

The number of ten - dimensional faces (10 - simplexes) of this polytope is $f_{10} = C_{n+1}^{11} = 78$.

The number of eleven - dimensional faces (11 - simplexes) of this polytope is $f_{11} = C_{n+1}^{12} = 13$.

Substituting the values f_i , ($0 \leq i \leq 11$) in the Euler - Poincaré equation (1), can to see that it holds for $n = 12$ for polytope on Figure 7

$$13 - 78 + 286 - 715 + 1287 - 1716 + 1716 - 1287 + 715 - 286 + 78 - 13 = 0.$$

This finally proves that the polytope D - ribose (A) has dimension 12 and a simplex type. Obviously, the polytope D - ribose (B) has the same dimension and type.

THE STRUCTURE OF THE DEOXYRIBOSE NUCLEIC ACID

The DNA is a chain of D - ribose molecules between which are the phosphoric acid residues that connect these molecules. Let us construct this circuit, taking into account the concept of repulsion of electron pairs (Gillespie, 1972; Gillespie & Hargittai, 1991). According to this concept, tetrahedral coordination of atoms and functional groups in these compounds is carried out around the phosphorus atom in the phosphoric acid residue, and in the carbon atoms in the D - ribose molecule also. It is this concept that leads to the higher dimensionality of the remainder of phosphoric acid and the molecule of D - ribose. When a phosphoric acid residue is added to the D - ribose molecule from the hydroxyl group of the phosphoric acid residue and the hydroxyl group of the D - ribose molecule, a water molecule that leaves the compounds forms and an oxygen atom that binds the phosphoric acid residue and the D - ribose molecule. The concept of repulsion of electron pairs also operates here, according to which two valence electrons of the oxygen atom maximally repel each other, forming electron pairs with electrons of the phosphorus atom and the carbon atom. Therefore, taking into account that tetrahedral coordination is carried out around the atoms of phosphorus and carbon already, it can assume that the valence bonds of the oxygen atom are located linearly with respect to the oxygen atom. When the second D - ribose molecule is added to the phosphoric acid residue, the second hydroxyl group of the phosphoric acid

residue with the compound CH_2OH of this *D* - ribose molecule also form molecules of water that leaves the compound and an oxygen atom connecting the phosphorus atom and the functional group CH_2 of the *D* - ribose molecule. By virtue of the concept of repulsion of electron pairs, the linear arrangement of the valence bonds of the oxygen atom can be considered here also. In addition, as the first step within the framework of the notions of the functional dimension of molecules (Zhizhin, 2016 b), can shall assume the linear arrangement of the valence bonds also in the neighborhood of the functional group CH_2 of the *D* - ribose molecule. One will take into account this when constructing a chain of DNA molecules and phosphoric acid residues. To construct the sequence of *D* - ribose molecules and the phosphoric acid residue in the chain can will use a simplified image of the *D* - ribose molecule of dimension 12. Let us leave only the outer contour and valence bonds necessary for interaction with the environment from the *D* - ribose molecule. (Figure 4 B). At the same time, one will not depict the hydrogen atoms inside the contour of carbon atoms. Also one approximately to consider that the lengths of chemical bonds carbon - carbon, carbon - oxygen close to each other. The image of the *D* - ribose molecule of the enantiomer form A under these conditions takes the form of Figure 8.

Figure 8. The simplified image of the enantiomer A of *D* – ribose molecule

The corresponding image of the *D* - ribose molecule of the enantiomer form B is shown in Figure 9.

Figure 9. The simplified image of the enantiomer B of *D* – ribose molecule

The absence of edges and atoms in Figure 8 and Figure 9 in comparison with the Figure 7 does not mean that they really are not. This is only the conventionality of the image.

It should be noted that under the assumed projection conditions, the *D* - ribose of molecules on a two - dimensional plane in which a closed carbon ring is located has a number of properties that are convenient for further constructions. The enclosed carbon ring is a regular pentagon with an internal angle at the vertices $\pi - \frac{2\pi}{5} = 108^\circ$. The angles in the three trapezoids formed by the valence bonds and the outer contour, because of the symmetry and parallelism of the bases, are 54 degrees and 126 degrees. In two obtuse - angled isosceles triangles formed by valence bonds and the outer contour, the angles are 126 degrees and 27 degrees.

Now, in a projection onto a two - dimensional plane, one shall depict a sequence of the simplified images of *D* - ribose molecules and phosphoric acid residues, taking into account the separation of water molecules at the junction of phosphoric acid residues and *D* - ribose molecules and the linear arrangement of the valence bonds in vicinity of these compounds. On Figure 10 presented the sequence for *D* – ribose molecules in form A.

Figure 10. Structure of the DNA molecule with D – ribose molecules in form A

On Figure 11 presented the sequence for *D* – ribose molecules in form B.

Figure 11. Structure of the DNA molecule with D – ribose molecules in form B

It follows from Figures 10 and 11 that the *D* - ribose molecules in both chains are not linearly distributed. Any sequence of corresponding points of *D* - ribose molecules in chains forms a curved line with rotation to the right side. However, in these sequences there is a fundamental difference. It is a consequence of the use in these two DNA structures of two enantiomeric molecules of *D* - ribose: the *D* - ribose molecule in form *A* in the DNA chain in Figure 10, the *D* - ribose molecule in the *B* form in the DNA chain in Figure 11. This difference consists in the fact, that in the DNA chain in Figure 10 the oxygen atom in the carbon ring of the *D* - ribose molecule is the extreme right in each *D* - ribose molecule. And in the DNA chain in Figure 11 the oxygen atom in the carbon ring of the *D* - ribose molecule is the extreme left in the carbon ring of the molecule *D* - ribose. It can be argued that the DNA structures in Figures 10 and 11 are enantiomeric DNA structures, which are a consequence of the presence of two enantiomeric structures of *D* - ribose molecules in them. The existence of two enantiomeric DNA structures was not noted before, since details of the arrangement of atoms in the DNA structures were not considered. Denote the structure of the DNA in Figure 10 of the DNA of the *EA*, and the structure of the DNA in Figure 11 of the DNA of the *EB*.

The projection of the DNA molecules depicted in Figures 10 and 11 can be described mathematically. Let us turn to a detailed picture of the connection of two nuclei (two *D* - ribose molecules of the form *B*) in Figure 11 (Figure 12).

Figure 12. Two nuclei of the DNA structure of the *EB*

The vertex *b* in this figure corresponds to the phosphorus atom, and the two edges emanating from it correspond to the projections of two valence bonds of the atom phosphorus with two oxygen atoms. They are at some angle γ on the projection. This angle characterizes the location of the residual phosphoric acid in space with respect to the *D* - ribose molecule *B* at the site of their connection (vertex *k*). It can be shown that the angle γ is linearly related to the angle $\Delta\alpha$ between two neighboring nuclei in the spiral chain of nuclei. Indeed, in Figure 12, the smallest distance between two corresponding points of two neighboring *D* - ribose molecules *B* in the chain Δh corresponds to the segment *OC*. The small-

est angle $\Delta\alpha$ characterizing the helical surface corresponds to the angle between the straight line that is the extension of the OC segment and the next segment CC_1 between two molecules of D - ribose, originating from the vertex C . The angle $\Delta\alpha = \angle ocb - \beta$, where $\angle ocb = \angle s_1cp$, β is the angle between segment OC and edge OS in the initial molecule D - ribose. The same angle is repeated in the next molecule of D - ribose. The angle $\beta = 54^\circ - \delta$ where 54° is the angle between edge OS and edge OK . The angle $\angle obc = \angle obk + \gamma$, but $\angle obk = \pi - \angle okb - \psi$, $\angle okb = 126^\circ$ by construction, therefore $\angle obk = 54^\circ - \psi$.

On the other hand $\angle ocb = \pi - \angle cob - \angle obc = \pi - (\delta + \psi) - \angle obk - \gamma = 126^\circ - \delta - \gamma$.

Therefore $\Delta\alpha = 126^\circ - \delta - \gamma - (54^\circ - \delta) = \frac{\pi}{5} - \gamma$.

An amazing result was obtained: the rotation angle between two molecules of D - ribose in the chain depends linearly only on the angle between the projections of the valence bonds in the phosphoric acid residue, that is, the orientation of the phosphoric acid residue in the space with respect to the D - ribose molecule

$$\Delta\alpha = \frac{\pi}{5} - \gamma. \quad (2)$$

Concordantly with model of Watson and Crick (Watson & Crick, 1953 a, b) in period of nuclei chain included 10 nuclei. In this chain the angle $\Delta\alpha = 36^\circ$. Therefore in this case, according to (2), the angle γ is also equal to 36 degrees. If in the period of nuclei chain include 12 nuclei (see Ha, et. el, 2005), so $\Delta\alpha = 30^\circ$, and $\gamma = 42^\circ$.

It is possible to calculate the minimum distance between the corresponding points of neighboring D - ribose molecules in the nucleic chain Δh . It follows from Figure 12 that $\Delta h = \sqrt{y_c^2 + x_c^2}$.

Values y_c, x_c are from the system

$$4(d+a)^2 \cos^2 \frac{\pi - \gamma}{2} = (y_e - y_c)^2 + (x_e - x_c)^2, (d+a)^2 = (y_b - y_c)^2 + (x_b - x_c)^2, \quad (3)$$

where $x_e = a(1 + \cos 54^\circ)$, $y_e = -a \sin 54^\circ$, $x_b = a(1 + 2 \cos 54^\circ) + d \sin 36^\circ$, $y_b = d \cos 36^\circ$.

The first equation of system (3) can be obtained from the equality of the square of the length of the segment ec to the sum of the squares of the differences of the coordinates of its vertices, on the one hand. On the other hand, the square of the length of the segment ec is the square of the doubled product of the cosine of the angle at the base of the isosceles triangle ecb by the length of the force side. The second equation of system (3) is obtained from the equality of the square of the side length cb to square of the sum of the segments a and d , on the one hand, and to the sum of the squares of the differences of the coordinates of its vertices, on the other hand. Solving system (3) for given a, d , one can find the value of Δh . To find the solution, the squares of the coordinate differences in the right-hand sides of the equations of system (3) are opened and the second equation is subtracted from the first. The linear connection of the coordinates of the vertex c is obtained. The equation of this connection is substituted into the second equation of system (3) and a quadratic equation is obtained for one of the coordinates of

vertex c . From two roots of the equation, the root corresponding to Figure 12 is chosen. Thus, for each value of the angle γ for given the values of a, d are the coordinates of the vertex c .

It is easy to verify that by mirroring the image on Figure 12 with respect to the bisector $b\theta$ of the angle γ passing through the vertex b , one can obtain an image of two coupled nucleotides corresponding to another enantiomeric form of DNA (Figure 10). In this way, the calculation of the parameters of the DNA structure according to the system (3) corresponds directly to two enantiomeric forms of the DNA structure. In the beginning, in order to find out the properties of the solutions of the system (3) corresponding to possible DNA structures, it can will numerically study these solutions, arbitrarily varying the value of the angle γ , which is the defining parameter of this system. Note that in this study it confine ourselves to analyzing one chain of a DNA molecule, although, as is known (Watson & Crick,

Table 1. The characteristic dimensions of the right and left DNA helices

Γ degree	$\Delta\alpha$ degree	N	Δh Nm	R Nm
36	36	10	0,4677	0,7447
42	30	12	0,501	0,9575
64,5	7,5	48	0,607	4,6397
72	0	∞	0,6394	∞
84	12	30	0,6815	3,2557
90	18	20	0,7	2
102	30	12	0,7337	1,4
108	36	10	0,7639	1,2163

Figure 13. Graphs of the change in the distance between nucleotides Δh , the angle of rotation between adjacent nucleotides $\Delta\alpha$, the number of nucleotides in the period N and the radius of the spiral $r = \frac{N\Delta h}{2\pi}$, depending on the angle α in the projection between the valence bonds of the phosphorus atom.

1953 a, b; Frank – Kamenetskiy, 1988, 2004, 2010), a DNA molecule consists of two or three chains of the DNA molecules connected to each other by hydrogen bonds. Such a connection of chains can be carried out in the future, relying on the obtained regularities of one chain.

Since, the lengths of chemical bonds between carbon - carbon and carbon - oxygen are ≈ 0.15 nm, can will adopt $a=0.15$ nm. The length of chemical bond phosphor – oxygen can will adopt $d = 0.18$ nm. The results of calculating the characteristics of the DNA structure from the equations of system (3) are shown in the graphs (Figure 13) and the numerical values of some parameters are given in the Table 1.

As can be seen from Figure 13 and Table 1 extension of the angle γ between the projections of the valence bonds of the phosphorus atom in the phosphoric acid residue from the angle of 36 degree to the plane of the carbon ring of the *D* - ribose molecule increases almost linearly the distance between the nucleotides in the DNA. In this case, the radius of the DNA helix increases nonlinearly asymptotically to infinity in the neighborhood of the value of the angle $\gamma = 72$ degrees. At a value γ of 72 degrees, the DNA molecule is straightened out into a straight line. With further increase in angle γ , the DNA helix begins to rotate to the left. In this range of values, increasing the angle γ also leads to an almost linear increase in the distance between nucleotides, but to a nonlinear decrease in the radius of the DNA helix. This occurs up to an angle $\gamma = 110$ degrees, at which the spiral turns into a closed ring, since there is no rise of nucleotides with the help of phosphoric acid residues. In cases where the angle is greater than 72 degrees $\Delta\alpha = \gamma - 72$. In Figure 14, as an example, an image of two adjacent nucleotides at 90 degrees is presented.

Figure 14. Two nuclei of the DNA structure of the EB for $\gamma = 90$ degrees

It can be seen from this figure that when γ is greater than 72 degrees, the angle $\Delta\alpha$ between two adjacent segments is laid to the left of the initial segment. This leads to the rotation of the spiral to the left.

Than from Table 1 can to see that for $\gamma = 36$ degree the distance between nucleotides in structure DNA $\Delta h = 0,4677$ nm. Wherein the number of nucleotides in the period is 10 and the radius of the spiral $r = 0,7447$ nm. To this value of the radius should be added the size of the phosphoric acid residue, which is along the length of the valence bond d and the angle between the valence bonds of 110 degrees $\Delta r = \sin 55^\circ d \approx 0.29$ nm. Then the radius of the DNA helix is $r + \Delta r \approx 1$ nm. The same DNA radius it was

observed in experiments (Watson & Crick, 1953 a, b) for 10 of nucleotides in the period. This form of DNA structure was designated B. From Table 1 can be seen that for $\gamma = 42$ degree the distance between nucleotides in structure DNA $\Delta h = 0,5$ nm. Wherein the number of nucleotides in the period is 12 and the radius of the spiral $r = 0,957$ nm. Then the radius of the DNA helix is $r + \Delta r \approx 1,35$ nm. These data roughly correspond to the form of the DNA structure, designated A. It is also known from experiments the existence of a DNA structure with 12 nucleotides in a period with left rotation (Ha, et al., 2005; Frank – Kamenetskiy, 2004). This form of DNA structure was designated Z. From Table 1 it follows that the value of the angle $\gamma = 102$ degrees corresponds to this form. The existence of DNA structures in the form of a closed ring has also been experimentally confirmed (Frank - Kamenetskiy, 2010). This form of DNA structure corresponds to the angle $\gamma = 110$ degrees in Table 1.

Thus, from the variety of solutions of the system (3) corresponding to the possible DNA structures, four forms of the DNA structure were experimentally confirmed. This does not mean that other forms of DNA structure that correspond to other solutions of system (3) do not exist. It should be assumed that these solutions have not yet been found in experiments, and in the future, when creating the appropriate conditions, they will be found. The received decisions should be considered also at consideration of forms of structures of DNA consisting of three connected spirals (form H) (Frank - Kamenetskiy, 1953 a, b). In addition, must not forget that each solution of the system (3) corresponds simultaneously to two enantiomeric forms of the DNA structure.

FUTURE RESEARCH DIRECTIONS

Further development of the accepted geometrical model of DNA structure with participation of elements of higher dimension - a residue of phosphoric acid and a molecule of *D* - ribose. In particular, to abolish some simplifying assumptions about the geometry of the chemical bond between the phosphoric acid residue and the *D* - ribose molecule.

To investigate the enantiomeric structures of DNA *EA* and *EB* by combining two or three DNA helices of a certain geometry into one compound using bases.

To investigate the effect of the chemical and physiological conditions on the geometric chemical bonds of the phosphoric acid residue and the *D* - ribose molecule.

Identify the features of the structure of RNA within the accepted geometric model.

To study the features of replication and translation for the protein synthesis in ribosomes, taking into account the developed geometric model of DNA.

Obtaining experimental data on the distribution of atoms and functional groups over the ribosome space would allow us to calculate the dimensionality of the ribosome space and to clarify the nature of the effect of this dimension on the processes of protein synthesis with given hereditary information.

CONCLUSION

The currently known forms of the helical structure of DNA molecules *A*, *B*, *Z*, and DNA molecules in the form of a closed ring were experimentally found in the works of Watson, J.D., Crick, F.H.C., Ha, S.C., Frank - Kamenetskiy, M. and other scientists. However, the reasons for the formation of such a different form of DNA molecules have not been clarified. In this paper is proved that the main reason for the formation of DNA molecules of different shapes is the different geometric realization of the

chemical bond between the phosphoric acid residue and the *D* - ribose molecule, as objects of higher dimensionality. In other words, the residues of phosphoric acid can geometrically act as a bridge, connecting the molecules of *D* - ribose with each other. It is shown that the angle γ between the projections of the valence bonds of the phosphorus atom in the phosphoric acid residue on the plane of the carbon ring in the *D* - ribose molecule is a parameter characterizing the various geometric forms of chemical bonding of phosphoric acid residues with *D* - ribose molecules. The angle γ characterizes the orientation of the phosphoric acid residue in the three - dimensional space. This parameter can therefore be regarded as an internal degree of freedom of the structure of the DNA molecule.

A mathematical model describing the geometric features of the chemical bond of these objects is constructed. Calculations on this model showed that the characteristics of known DNA structures, determined experimentally, and calculated from the constructed model, are in good agreement with each other, while the model does not contain any empirical parameters. Calculations show that known DNA structures are particular cases in the model and it can be considered that known examples of DNA structure forms are experimental confirmation of the correctness of the mathematical model. However, according to the mathematical model, its solutions are many other DNA structures that have not been experimentally discovered so far. One can hope that their experimental discovery is ahead.

The existence of two enantiomeric forms of DNA molecules, connected with the existence of two enantiomeric forms of *D* - ribose molecules, is established.

The resulting variety of DNA molecule structures is represented in the form of analytical dependencies, graphs and table.

They should be taken into account when analyzing the synthesis of proteins, replication and translation of DNA in the work of ribosomes (Stewart & McLachlan, 1975; Spirin & Gavrilova, 1971; Spirin, 1986).

The high dimensionality of the constituent DNA molecules unites the problems of the DNA molecule structure with the Big Data problem, which has become widespread in computer science recently in describing a variety of complex phenomena (Rodger, 2015).

More Plato suggested that objects of Nature, their quality and operating between the forces, may be the result of exposure to hidden from us the geometric structures (Yau & Nadis, 2010). In recent decades, a shining example of the opening of the geometric structure is string theory. Based on the solutions of Einstein's equations, this theory postulated that the manifold of higher dimension hidden in every point in space (Colabi -Yau manifold of dimension 6). It has vanishingly small size. In the nanoworld, as shown in (Zhizhin, 2014 a, b; Zhizhin, 2015 a, b; Zhizhin & Diudea, 2016; Zhizhin, Khalaj & Diudea, (2016); Zhizhin, 2016 a, b) is also a hidden dimension but objects (especially molecules), having these dimensions, are tangible sizes. A common basis for understanding the hidden dimensions of the objects of nature, and in string theory, explains the structure of the universe and the structure of elementary particles (Green, 2000; Gepner, 1988), and in the theory of the nanoworld is Riemann geometry (Riemann, 1854), allowing the existence of spaces of higher dimension in the space of lower dimension.

The higher dimensionality of the constituent DNA molecules, which allows to describe mathematically the structure of DNA, requires reconsidering the issues of tight packing of DNA molecules in cells, viruses and bacteria, provided that the DNA chains necessary for the preservation and transfer of genetic information are complementary.

KEY TERMS AND DEFINITIONS

Deoxyribonucleic Acid: A biopolymer, the monomer of which is the nucleotide.

Dimension of the Space: The number of independent parameters needed to describe the change in position of an object in space.

Nucleotide: A phosphoric acid residue attached to sugar deoxyribose, to which one of the four nitrogen bases is attached also.

Polytope: A polyhedron in the space of higher dimension.

Simplex: A convex polytope, any two vertices of which are joined by an edge.

INTRODUCTION

“Can machines think?”, this is the question that Turing (1950) put forward already in 1950. It is possible to consider the discussion in that article as a starting point in history of what nowadays is called Artificial Intelligence (AI), although, previous to that time, there are some works that could be considered as what is now called AI.

Already in antiquity, philosophers and thinkers in general had advanced the idea that “mechanical men” could be constructed and they would be able to mimic human beings in action and thought. So it could be said that the concept of artificial intelligence has existed for a very long time previous to 1950, the approximate date considered here as the start of what is now referred as AI.

AI has had from the 50s a fruitful history. Along the years several branches have emerged such as Machine Learning, Data Mining, Robotics, Statistical Learning, Deep Learning and others. Research on the subject and the development of tools and methods have grown significantly, specially over the past twenty years. The constant search for the causes of diseases, the improvement of automatic diagnoses methods, financial data analytics and market tendencies, among others, are only some of the innumerable applications where analysis and discovery of new patterns have fuelled the research and development of new methods, all related to Machine Learning, knowledge extraction from what is now being called Big Data, Knowledge Discovery in Databases or KDD, and Data Mining. This chapter focuses on Data Mining methods and algorithms as approaches to different learning tasks. The relationship of Data Mining with other disciplines inserted in the area of Artificial Intelligence is also analyzed, as well as a brief discussion on issues associated to the discipline and future research directions are also presented.

BACKGROUND

Theoretical discussions about the possibility of creating automatons or supposedly intelligent machines have been coming for a long time. In Ernst & Newell (1969) a research was conducted on the development of a computer program with general problem-solving capabilities. The program could solve problems like the Tower of Hanoi or prove theorems in first-order predicate calculus.

Weizenbaum, J. (1976), author of a then well-known computer program initially called ELIZA and later DOCTOR that allowed parodying the role of a Rogerian psychotherapist, was surprised, he says, for three events: (i) A number of psychiatrists thought that the program could become an automatic form of psychotherapy. (ii) How quickly and deeply people became emotionally involved with the program. (iii) The dissemination of the belief that the program showed a general solution to the problem of understanding natural language by computers. This situation reported by Weizenbaum can be compared

DOI: 10.4018/978-1-7998-3479-3.ch051

with The Turk, the well-known chess player who for decades, from the end of the 18th century until the end of the 19th century, was believed to be a machine capable of playing chess. This, and many others around the same time, can be predecessors of programs that nowadays are considered to be part of the general field of AI.

In his textbook Wiston (1977) says that “The central goals of AI are to make computers more useful and to understand the principles which make intelligence possible”.

Many authors agree that AI is an important knowledge area that is closely related to other disciplines. As Russell, S. J. & Norvig, P. (2010) express, “Artificial Intelligence (AI) is a big field ... which encompasses logic, probability, and continuous mathematics; perception, reasoning, learning, and action; and everything from microelectronic devices to robotic planetary explorers”. AI comprises not only Machine Learning but other disciplines such as Robotics, Logic Programming and Inductive Logic Programming (ILP), a field of Machine Learning and Data Mining. These different areas could conceivably be either form part of AI or have sprout from it.

AI has had different goals along its history. Initially the idea embodied in Turing’s question was paramount. Could a computer be built that acts like a human being?, hence, could it solve the problems that a human could? Several tests were developed to assess such ability. Turing (1950) put forward what is now called the Turing Test, but that he called the ‘The Imitation Game’. On the Turing Test there are different opinions. Cohen, Paul R. (2006) summarizes them saying that there are three kinds of arguments against Turing’s test, namely some say that the test is irrelevant, it should be forgotten, get rid of it, however it still stands today. There are competitions, variations on the test, etc. Another argument against the test is related to the philosophy connected to the question of whether machines can think, or what is thinking and if machines really can do it or is it just a simulacrum. Others give a methodological argument when asking the question. is the Imitation Game, –as Turing put forward– a valid methodological means of definitely determining whether a machine can think?, “They argue that the test is methodologically flawed and is based in bad philosophy, that it exposes cultural biases and naïveté about what Turing calls the “programming” required to pass the test.” Cohen, Paul R. (2006, p. 61). For more on the Turing test see Hernández-Orallo, J. (2000).

AI has greatly evolved since Turing’s paper times. That evolution has boosted the development of different branches, stimulated by practical concerns such as pattern recognition, data analysis and knowledge discovery. One of these areas is Data Mining, in which this chapter is focused.

The development of some AI fields has benefited from the existence of large volumes of data proceeding from the most diverse sources and domains. The Knowledge Discovery in Databases (KDD) process and methods of Data Mining allows for the discovery of knowledge in data that is hidden to humans, particularly when data volumes are large or even extremely large. These methods present the knowledge extracted under different ways: rules, equations, decision trees, etc., and help in answering questions such as what are the groups from a population of individuals with common characteristics?, is a client reliable?, is an e-mail spam?, etc.

Answers to these kind of questions are different from those obtained from traditional queries in On Line Transactions Processing (OLTP), where the information is not hidden neither is discovered, but it is summarized in an agreed format or report. They also differ from information proceeding from Online Analytical Processing (OLAP), which can be presented in different perspectives or aggregated in different ways and not just summarized as in OLTP, and that can even escalate to the use of big data, where OLTP fails. However, both of these methods are not capable of discovering new knowledge neither producing new patterns nor rules as the KDD process permits.

This chapter focuses on the Data Mining phase of KDD process, its tasks and methods, as well as its relation to other areas of AI such as Machine Learning, Inductive Logic Programming, Statistics, etc. A discussion on issues and challenges associated to the field is given and some future research trends are presented.

DATA MINING, MACHINE LEARNING AND ARTIFICIAL INTELLIGENCE

The notion of Data Mining is not new. Since the 60s, other terms as Data Fishing or Data Dredging have been used by statisticians to refer to the idea of finding correlations in data without a previous hypothesis as underlying causality. However, it is not until the late 80s that Data Mining became a discipline of Computer Science and scientific community adopted the term. In fact, as Witten and Frank (2011) point out, the first book on data mining appeared in 1991 (Piatetsky-Shapiro and Frawley, 1991) –a collection of papers presented at a workshop on knowledge discovery in databases in the late 1980s.

Data Mining is a branch of AI closely related to Machine Learning, where Machine Learning provides the technical basis for Data Mining (Witten and Frank, 2011). Data Mining deals with inductive learning in a practical and not theoretical way (as Machine Learning does), making use of tools provided by Machine Learning. It applies Machine Learning techniques as well as other statistical and algebraic techniques to find structural patterns hidden in data, with the main objective of describing data or making predictions from them.

Figure 1. Data Mining and other related disciplines

AI comprises not only Machine Learning but other disciplines such as Robotics, Logic Programming and Inductive Logic Programming (ILP), which is a field of Machine Learning and Data Mining. Figure 1 shows a schematic view of the relationships between Data Mining, Machine Learning, AI and other associated disciplines.

DATA MINING AND THE KDD

Several definitions of Data Mining can be found in the literature. Witten and Frank (2011) refers to Data Mining as the process of extraction of previously-unknown, useful and understandable knowledge from big volumes of data, which can be in different formats and come from different sources. Hernández-Orallo, Ferri and Ramírez-Quintana (2004) define Data Mining as the process of converting data into knowledge. However, there is still some confusion in the use of the terms ‘KDD’ and ‘Data Mining’. Although they are strongly related, they are not the same. Data Mining is a phase in the KDD process, an iterative process that encompasses other phases or activities as the selection, cleaning and transformation of data, coming not only from traditional databases but also from other heterogeneous sources, such as plain text, data warehouses, images, sound, etc. The application of data mining algorithms to these data is achieved to discover valid, novel, potentially useful, and understandable hidden patterns. Once patterns are obtained, they are interpreted and evaluated, going back to previous phases for a new iteration if necessary.

Figure 2 shows a graphical representation of the KDD process. Some authors decompose KDD into other phases; nevertheless, its activities are basically the same.

Figure 2. The KDD process

During the Data Selection/Sampling phase, activities that have to do with data collection and integration take place. Frequently, data are collected from the most diverse sources hence they do not share the same format and structure. In these cases, an activity of data integration is required. This has given place to the concept of data warehouse, a technology used by organizations to collect data from different sources for the purpose of analysis and decision making, e.g. evolution forecast, organizational analysis, and strategy design.

Unlike databases, mainly used by applications based in traditional processing of data, known as OLTP (On-Line Transaction Processing), data warehouses are operated by OLAP (On-Line Analytical Processing) tools. Data warehouses have a different data organization from databases, adopting a multidimensional data model.

Like OLAP, Data Mining techniques can make use of data from data warehouses, but while OLAP tools allow aggregating detailed information, getting reports and views in real time and verifying patterns and hypothesis suggested by the user in an essentially deductive process, Data Mining methods are essentially inductive process that uses data to infer patterns. Nevertheless, OLAP tools can also be used in the first stages of the KDD process for a better understanding of data.

A second phase of Preprocessing/Cleaning and Transformation is sometimes needed. During this stage, a minable view of the previously integrated data is created. A minable view is a subset of the integrated data that will be input to the data mining algorithms; it eliminates the unnecessary data for the data mining task. To that effect, activities such as the creation of new attributes, selection of relevant attributes, attribute transformation and reduction in the number of observations can also take place. Sometimes, missing values and outliers (anomalous values) are also eliminated, especially when the algorithm used is sensible to their presence.

Once the minable view is ready, the Data Mining phase can proceed. In this phase, decisions about the method or technique (e.g. decision trees) to adopt for solving a task (e.g. classification) must be taken. In this phase the algorithms to be applied to the minable view (e.g. CART, C4.5) must be chosen. In the next sections an overview of Data Mining's tasks, methods and algorithms is given.

The last phase, Evaluation and Interpretation of patterns, is where the model learnt from data mining is evaluated, after which a new iteration begins starting from one of the previous stages whenever it is necessary.

Evaluation is a very important process in KDD since it involves determining which of the models among several alternatives is going to be kept for solving the problem at hand. Therefore, techniques to evaluate how well the different methods work and to compare them are indispensable.

Model evaluation techniques and measures depend on the kind of task to solve (descriptive/predictive). For example, a typical evaluation measure for classification models is error rate/accuracy, defined as the proportion of incorrectly/correctly classified instances over the total number of instances.

The most simple evaluation technique for predictive tasks is simple validation, where the evidence is split in two sets, one for testing (test set) and the other for training (training set). This is done to guarantee that the evaluation measure obtained from the test set is an independent measure, avoiding too optimistic estimations. However, there exist most sophisticated techniques such as cross validation, n-fold cross validation, useful when the evidence is scarce, or bootstrapping (Efron and Tibshirani, 1993) (Kohavi, 1995).

In descriptive tasks, such as clustering and association rules, different measures are used. For example, coverage (or support) and accuracy (or confidence) are used for association rules.

TASKS AND METHODS OF DATA MINING

A task is normally defined as a work that is assigned to a person. In the realm of AI a task is work that will be assigned to a machine or computer, and a better definition would be a work that will be done by a computer program.

A method is a procedure, technique, or algorithm for doing something: in this case a task. The main method that AI and its different branches use to accomplish the tasks is Inductive Learning (IL). In the following sections both tasks and methods of Data Mining are detailed.

DATA MINING TASKS

In AI, as in many other disciplines, there exist families of problems. Each of these families, is called learning task and it can be solved by means of diverse methods and algorithms. Pattern Recognition like image recognition –including face recognition–, text recognition, etc. can be considered one of the main tasks. But Classification, regression, clustering, correlations and association rules, can also be recognized among the most important of these tasks.

As result of a task and according to the problem it solves, a prediction or a description can be obtained, giving place to predictive and descriptive tasks. Predictive tasks, as its name indicates, estimate unknown or future values, while descriptive tasks search hidden patterns in data as a way of explaining or describing them.

One of the most common predictive tasks is classification, while correlations, association rules, functional dependencies and clustering can be considered as descriptive tasks.

A classification task consists in labeling each new instance with a tag (the class), from a set of possible classes. Classification predicts the class of an instance from the values of its attributes, e.g. a classifier that has previously learned the concept of spam from old messages labeled as spam/no spam can be used to classify new messages.

There are variations to classification like categorization, where an instance can be labeled with more than one class. Other variants to classification are soft classification and probabilistic classification. A soft classifier not only assigns a class but also an estimation of the degree of certainty. Probabilistic classification is a generalization of soft classification, where for each instance the classifier predicts a probability distribution for the set of possible classes. When the number of classes are two, a probabilistic classifier is equivalent to a soft classifier.

Another descriptive task is preference learning, where a ranking is learnt. The learning process is carried out not from a set of instances like in classification but from a set of sequences of instances, where the order in a sequence represents the preference order of the instances in the sequence. For example, given a set of candidates for a job position, to get a preference order of the candidates based on their attribute's values and previous preference rankings from which to learn the new preference order.

Regression is also another important predictive task. In this case, a real value is predicted, i.e., a real function is learnt. An example of a regression task is the productivity estimation for a company based on past productivity values. When a real value is predicted for the future, this task is referred as estimation, and when the real value predicted is between two known values it is referred as interpolation.

On the other hand, correlation is a descriptive task. It is useful to determine whether two numeric variables are correlated, i.e. whether they have a similar behavior. When there is a positive correlation, both variables increase and decrease at the same time; if the correlation is negative one decreases when the other increases. A correlation not only can be positive or negative but it also can be strong or weak or nonexistent. This task is used in data mining to determine redundant attributes or dependencies among them.

Association rules is also a descriptive task that, as correlations, finds existing relationships among categorical (non numerical) attributes. Functional dependencies are a variation of association rules, where

only one attribute is determined from a subset of the remaining attributes. For example, a functional dependency could determine that a person is a homeowner from his/her age, income and marital status.

The descriptive task of clustering consists in partitioning a set of instances in natural groups called clusters. Originally, the central concept for clustering was the use of a numeric measure of similarity between the instances, creating clusters where the similarity among the members of a cluster is maximized and the similarity between the members of different clusters is minimized. A different approach to clustering is conceptual clustering proposed by Michalski (1980), which is not based in the notion of similarity but in conceptual cohesion (Michalski and Stepp, 1983). In conceptual clustering, two individuals belong to the same cluster not because they are similar (according to a similarity measure or distance) but because they are part of a same concept or, in other words, they are described by a same concept. These two different views of clustering have given place to different approaches to this task: similarity based clustering and conceptual clustering.

The main application of clustering is in guessing that new instances that have been considered members of a cluster have similar behavior or characteristics that the members of that cluster. For example, an on-line shop could make use of clustering to create groups of customers according to their purchase preferences, and then when a customer buys an article the system offers other articles based on the preferences of others customers in the same cluster.

DATA MINING METHODS AND ALGORITHMS

There is an important number of learning methods that support the previously described tasks. For example, a classification task can be solved using different methods, e.g. neural networks or decision trees. At the same time, each particular method can be implemented by different algorithms. For example, there are several decision trees algorithms, such as ID3 (Quinlan, 1986) or its extension C4.5 (Quinlan, 1993). Many of them can be used to solve different tasks, e.g. k-nearest neighbor algorithm can be used for classification, regression and also for clustering.

In general, DM methods can be categorized as supervised and unsupervised. Supervised methods learn models from examples, where there is a teacher or supervisor (expert) who defines the classes and provides examples for each class. These examples form a training set, which is used to build a model that allows predicting the class of new examples. Some supervised methods learn a function, i.e. the class are disjoint, while others learn a relationship, where classes can be overlapped. The first corresponds to the task of classification, while the second to categorization.

In unsupervised methods, learning is by observation and discovery; the examples used for learning are not labeled with a class as in supervised methods but the method must observe the examples and recognize patterns by themselves.

In general, both supervised and unsupervised methods adhere to one of two inductive learning approaches: symbolic learning and similarity-based learning. In the next section a description of both approaches and an overview of their main methods are given.

SIMILARITY-BASED LEARNING

Similarity-base learning methods share the concept of similarity and other associated concepts like the notion of distance and neighborhood or proximity. Some kind of mechanism is needed to compare two

objects and decide if they are similar. One way is by means of the use of a similarity function. A similarity function is a real function that given two objects returns a real value representing how similar these two objects are; it returns higher values while more similar the objects are. For example, a similarity function frequently used in Machine Learning is the cosine similarity measure between two vectors of real numbers; it is often used to compare documents.

The concept of distance or metric is associated to the notion of similarity, being the distance between two objects inversely proportional to the similarity between them. Even though a distance is a particular case of a similarity function, distances have certain properties that can be advantageously used by learning techniques.

Similarity-based methods support the idea that similar objects should behave in similar way. For example, given a similarity measure, a new instance could be classified as belonging to the class that has the most similar instance; or in a clustering task, it could be placed it into the cluster that has the instances more similar to it.

A brief description of some well-known similarity-based supervised and unsupervised methods follows.

SIMILARITY-BASED SUPERVISED METHODS

Similarity-based supervised methods learn from a set of labeled instances employing a similarity function or a distance to make their predictions. Examples of them are k-Nearest Neighbors, Fisher's discriminant, Support Vector Machines, Learning Vector Quantization, among others.

k-NN (k-Nearest Neighbors)

It is very simple and probably the best-known supervised method. The idea behind k -NN is that the k nearest neighbors' majority class is assigned to each new instance. The main problem is determining the optimum value for k (see Figure 3). Usually, k is determined using heuristics; however, $k = \sqrt{n}$ where n is the number of examples, is an option with a theoretical base.

Figure 3. Difference between the nearest neighbor classifications in function of the chosen value of k

Any data representation can be used provided that a suitable similarity function is found.

Support Vector Machines (SVM)

This method searches a linear discriminant that maximizes the distance to the examples in the border of a class.

The classifier simply computes the hyperplane that perfectly separates the classes and that maximize the distance from the examples in the class border to the frontier (see Figure 4).

Figure 4. Linear discriminants

SVM are very efficient, even for hundred of dimensions because the linear discriminant has only to see a few points, called the support vectors, avoiding all the points that are not close to the frontier.

When data cannot be lineally discriminated (see Figure 5), a *kernel* function can be applied, augmenting the number of dimensions in such a way that the data are separable.

Figure 5. Set of examples not lineally separable

A SVM model is a representation of the examples as points in a space, transformed in such a way that the examples are clearly separated. When a new example must be classified, this is transformed by the kernel function into the same space and classified according to the side of the hyperplane where the new example falls.

Learning Vector Quantization (LVQ)

The learned model is a collection of prototypes, where a new example is classified according to its proximity to those prototypes. A prototype of a set of elements is the element of the set that is in the center of the elements according to its metric space; i.e. it minimizes the sum of the distances to the other elements in the set. When this element does not belong to the set, it is called centroid.

Given a training set with k classes, the algorithm randomly choose k prototypes, whose positions change until a given threshold is reached. This is an iterative process, where, firstly, an example from the training set is chosen and labeled with the class of the closer prototype. Next, the prototype of the class is recomputed. Depending on the labels of the prototype and the example, the prototype position will change, making closer the new prototype to the example if both labels match or the opposite if they do not match. The process stops when the change in the prototypes positions is lesser than a give threshold or there are no more training examples.

SIMILARITY-BASED UNSUPERVISED METHODS

In similarity-based unsupervised learning, the evidence is presented as a set of unlabeled elements and the objective is to find a descriptive model from the evidence, in this case using a similarity function.

Learning of descriptive models can be carried out in different ways and by multiple tasks, e.g. clustering, correlations and factorizations, association rules and functional dependencies.

A brief description of similarity-based clustering methods is given below; the presented clustering methods have been classified into hierarchical clustering and partitioning clustering, a common classification of clustering methods.

Hierarchical Clustering

These algorithms produce nested series of partitions of the evidence using as criterion, for splitting or merging the clusters, a similarity function. Well-known examples of hierarchical clustering are agglomerative and divisive hierarchical clustering.

A hierarchical algorithm produces as result a dendrogram, which represents the nested clusters. It also shows the similarity levels where a clustering changes to a new clustering (see Figure 6).

A dendrogram can be decomposed at different levels obtaining different data partitions. For example, in Figure 6, the dotted line cuts the hierarchy at the level corresponding to the clustering formed by the groups $\{A, B, C\}$, $\{D, E\}$ and $\{F, G\}$.

Figure 6. Example of dendrogram produced by a hierarchical clustering algorithm

Partitioning Clustering Algorithms

Unlike hierarchical clustering algorithms, which create a clustering hierarchy, these algorithms produce only one partition of the evidence.

One of the most well-known partitioning algorithms is k-means. Its process begins with an initial random partition formed by k clusters and proceeds reassigning the examples to other clusters driven by the distance between the example and the clusters' centroids. Once all the examples have been reassigned, the clusters' centroids are recomputed. This process continues until a convergence criterion is reached. Although k-means is popular because its implementation is simple, it has the drawback of being sensitive to the selection of the initial partition.

MODEL-BASED SYMBOLIC LEARNING

A weakness of similarity-based methods is the lack of interpretability of the discovered models, which are determined by the similarity between the evidence elements. This makes these models hard to understand by humans. However, in many cases to have an explicative model is a must; for example, a learned model should provide an explanation or description of its recommendations when refusing a loan to a customer, going beyond a label that classifies the customer as unreliable. It is here where symbolic methods are useful. In the next two sections some of these methods are described.

MODEL-BASED SYMBOLIC SUPERVISED METHODS

Possibly, the most well-known supervised symbolic method is decision trees, where a predictive model in the shape of a tree structure is learnt from the evidence. Decision tree branches represent attributes conjunctions and its leaves correspond—in the case of classification trees—to a set of labels or classes, or to real values in the case of regression trees.

Figure 7 shows a decision tree produced by the J48 algorithm in the Weka toolset (Weka, n.d.) induced from its weather dataset. Given a new instance, it allows ascertaining whether to play a tennis

match. The tree shows in its intermediate nodes the attributes outlook, humidity, and windy with their corresponding values on its arcs and the values yes/no of the class (play), on the leaves.

Figure 7. Decision tree to determine whether to play tennis

Whenever a new instance must be classified, the tree is traversed from the root according to the attribute values in the successive nodes until a leaf is reached and the instance is classified with the value in the leaf.

MODEL-BASED SYMBOLIC UNSUPERVISED METHODS

Two representative unsupervised symbolic methods are Conceptual Clustering (Michalski, 1980), (Michalski and Stepp, 1983) and Formal Concept Analysis (FCA) (Ganter et al., 1999).

Conceptual Clustering

Classical distance-based unsupervised learning methods do not provide conceptual descriptions of the discovered clusters. This is a limitation of these methods that leave to the user the problem of interpreting clusters.

Michalski introduced, in 1980, the idea of grouping objects in categories that are described by concepts. As it is explained in (Guerra-Sandón et al., 2012), the problem addressed by conceptual algorithms is of great practical usefulness. They are not limited to produce a list of objects that are in the same cluster and hence share similar characteristics or properties, but the intention of conceptual clustering is to provide additional information by giving the common properties of the elements in each cluster.

Michalski was the precursor of these ideas and nowadays there are several algorithms for conceptual clustering. A conceptual clustering classification is given in (Guerra-Sandón et al., 2012). There also exists hybrid proposals like HDCC (Funes et al., 2008), where an integration of both paradigms is achieved.

Formal Concept Analysis (FCA)

FCA allows identifying conceptual structures from data. These structures correspond to lattices of formal concepts, where each formal concept is a pair (set of properties, set of examples) and where the set of properties in the formal concept describes completely its set of examples. These lattices of formal concepts consist of a partial order relation defined as a generalization relation between formal concepts. The main objective of FCA is offering compact descriptions of groups of data rather than a data clustering.

NEURAL NETWORKS

Artificial Neural Networks (ANNs) have a long history, quite as long as AI itself. They were inspired by the functioning of biological neurons. Basically, neurons in a brain are interconnected by axons. A neuron receives inputs from other neurons and when those inputs exceed a threshold the neuron sends an output to other neurons. Artificial Neurons (AN) mimic the functions of 'real' neurons. Each AN is

Figure 8 (a) Perceptron (single layer). (b) Multiple Layer ANN

a mathematical function $y = f(\sum_i (x_i w_i))$ where x_i are the inputs and w_i the associated weights. Figure 8 (a) shows a particular ANN, called Perceptron, which has one AN its inputs, weights and its output.

The origins of ANNs can be found in the work of McCulloch & Pitts, (1943), who first constructed a theory of AN that gave way to the Threshold Logic Unit (TLU), or Linear Threshold Unit. Later, Rosenblatt (1957) created the Perceptron. Initially, it was intended as an algorithm for supervised learning of binary classifiers, later it was implemented as a machine for perceiving and recognizing images. The Perceptron was a single layer ANN. Later Minsky & Papert (1969) showed that single layer ANNs –like the Perceptron– are unable to perform a logical xor.

The next advance was the creation of ANNs with multiple layers, i.e. ANNs that have an input layer, an output layer and one or more intermediate layers called hidden layers since they cannot be ‘seen’ from the outside (see Figure 8 (b)).

An ANN can be trained to accomplish a task. An important improvement in ANN training was the introduction of the technique of backpropagation, an efficient method for calculating the weights updates to improve the network until it is able to perform the task for which it is being trained (Goodfellow et al., 2016). There is a bit of a controversy on the discovery of the method but some of the pioneers in the area are Kelley (1960), Bryson (1961), and then Mizutani, Dreyfus, & Nishio (2000).

Learning algorithms for ANNs can be supervised or unsupervised. When the desired output is given to the ANN input layer is supervised. Unsupervised learning provides unlabeled data and the algorithm tries to make sense of it by extracting features and patterns on its own. There are also semi-supervised learning algorithms, where normally only a small labelled set of data is provided against a large set of unlabelled data.

A more recent and growing branch of Machine Learning is Deep Learning, which implies the use of ANNs with multiple layers. These neural architectures come in a number of varieties such as convolutional neural networks, deep neural networks, deep belief networks, recurrent neural networks and others. They are applied to many fields e.g. image and audio recognition, natural language processing –including machine translation– social network research, bioinformatics, drug design, image analysis, game programs, etc., where they produced results comparable to and in some cases superior to human experts. ANNs for Deep Learning are sometimes called Deep Neural Networks (DNN). DNNs are huge ANNs, whose current upper number is in the range of 100-160 billion of ANs.

ISSUES, SOLUTIONS, AND RECOMMENDATIONS

Along the last the years several issues regarding Ethics, mainly related to self-driving vehicles and autonomous weapons, both areas where AI is being used, have arisen.

As Maxmen (2018) said “When a driver slams on the brakes to avoid hitting a pedestrian crossing the road illegally, she is making a moral decision that shifts risk from the pedestrian to the people in the car”. So that moral burden on a human driver shifts now to the software and hardware in a self driving vehicle. Considering that the software and hardware are built by humans, some of the questions are: what kind of moral decision is built, programmed, into the AI program that drives the vehicle, since there are situations, around a particular maneuver of the vehicle, that may involve a moral decision? Who is legally responsible for the damages –including loss of life– to third parties involved (passengers and bystanders included) in an accident of a self-driving vehicle? These questions will necessary have to be answered.

Also the building and deploying of autonomous weapons is of great concern and has lead to a debate on the subject by prominent researches in the AI field, exposing pros and cons clearly. For more infor-

mation on this, see Scharre & Horowitz, (2015), Russell, Tegmark & Walsh, (2015), Ackerman, (2015), Gubrud, (2016), Guizzo & Ackerman, (2016), Scharre, (2017), Russell, Aguirre, Conn & Tegmark, (2018).

Another important problem intimately associated with Data Mining and AI is privacy and protection of personal data. While these disciplines have benefited from the existence of large volumes of data from diverse sources, these data are not always legally obtained. The laws and regulations related to privacy and data protection varies around the world and are constantly changing in the search of a balance between rights of individuals and other interests.

FUTURE RESEARCH DIRECTIONS

More and more are the areas where AI and Data Mining are having great impact and where some related research is being conducted. Below a short sample of what can be considered part of the future research directions on the field of AI is given.

Companies such as Jobscan (2019) that provides job seekers with help in improving their resume, claim –based on their own data– that over 98% of Fortune 500 companies use Applicant Tracking Systems (ATS), based on AI. Also Korn Ferry (2018), a consulting firm in Los Angeles, USA, states something similar.

Using the concept of Neuromorphic, proposed by Mead (1990), Intel is planning to build a Neuro-morphic System of 8 Million Neurons and to reach 100 Million by 2020, Moore, (2019).

Javed et al (2019) use AI and Robotics to help children with Autism Spectrum Disorder.

Not only image and face recognition is a growing area of research, but also recognition of fake images is also an area where AI is being used, see Leopold, (2019).

CONCLUSION

Although AI has become a mature discipline and Data Mining has contributed greatly to technological development in recent years, the question remains: Is building a human-like computer a valid goal of AI? This question intends to be answered by proposals such as technological singularity, sometimes referred only as singularity, a concept first put forward by Vinge (1993). Basically the concept holds that the technological progress will eventually lead to the creation of a superhuman intelligence and the consequently demise of the human era. Or Technium is another term, in this case coined by Kelly (2010), used “to designate the greater, global, massively interconnected system of technology vibrating around us” Kelly (2010, p. 11). This notion has been criticized as having a certain religious bias, but also by the continuous application of AI to different areas that were before reserved for humans.

Beyond the aforementioned philosophical question, AI continues to occupy places previously reserved only for man. This leads us to rephrase the question: Is it in this trend that the answer can be found?

KEY TERMS AND DEFINITIONS

AI4Good: By building lasting communities that bring the best technologies to bear on the world's most important challenges, the AI for Good Foundation drives forward solutions that support the United Nations Sustainable Development Goals (SDG's). We do this by coordinating the AI research commu-

nity, technologists, data, and infrastructure with the stakeholders on the ground, policy makers, and the broader public (<https://ai4good.org/about/>).

Automated Reasoning: To use stored information to answer questions and to draw conclusions.

Classification: Inductive task where a predictive model is learnt from objects labeled with a class and whereby it is possible to predict the class of new objects.

Cloud Computing: Generally refers to describe data centers available to many users over the Internet that provide data storage and computing power. It's sometimes used to process DNNs.

Clustering: Inductive task where a set of unlabeled objects is partitioned into groups (clusters) and where objects in a same cluster have similar characteristics, maximizing the similarity intra cluster and minimizing the similarity inter cluster.

Inductive Learning: Induction is the inference of information from data and inductive learning is a model building process where the data are analyzed to find hidden patterns.

Machine Learning: The study and use of algorithms and mathematical and statistical models in computer systems to perform a specific tasks but not using explicit instructions, on the contrary relying on discovery of patterns and inference. Is considered part of Artificial Intelligence. The software is to adapt to new circumstances and to detect and extrapolate patterns.

Natural Language Processing: The software is to be able to communicate successfully in a Natural Language (e.g., English).

Robotics: The machine should be able to manipulate objects and move about.

Weak AI: Also known as Narrow AI is AI aimed at a particular task.

Big Data Mining Algorithms

M. Govindarajan

Annamalai University, India

INTRODUCTION

Data mining is widely used in fields such as science, engineering, medicine, and business. With this technique, previously hidden insights have been unearthed from large amounts of data to benefit the business community (D. Che et al., 2013). Since the establishment of organizations in the modern era, data mining has been applied in data recording. For flexible data analysis, Begoli and Horey (2012) proposed three principles: first, architecture should support many analysis methods, such as statistical analysis, machine learning, data mining, and visual analysis. Second, different storage mechanisms should be used because all of the data cannot fit in a single type of storage area. Additionally, the data should be processed differently at various stages. Third, data should be accessed efficiently. To analyze Big Data, data mining algorithms that are computer intensive are utilized. Such algorithms demand high-performance processors. Many algorithms were defined earlier in the analysis of large data set. The purpose of this chapter is to provide an analysis of different machine learning algorithms available for performing big data analytics.

BACKGROUND

C. Yadav et al., (2013) present a review of some old algorithms that can handle large data set as Nearest Neighbor Search, Decision Tree and Neural Network. A. Fahad et al., (2014) present a survey of existing clustering algorithms of different categories (Partitioning-based, Hierarchical-based, Density-based, grid-based and model based). Tsai et al., (2015) begins with a brief introduction to data analytics followed by the discussions of big data analytics. Some important open issues and further research directions will also be presented for the next step of big data analytics. D.Rajkumar and S.Usha (2016) review on various big data mining algorithms and the methods employed to handle such a vast data is also discussed. J. Sangeetha and V. Sinthu Janita Prakash (2017) surveys about the big data mining techniques, data slicing techniques and clustering techniques and also discusses about its advantages and drawbacks. The performance and quality measurement of the big data mining algorithms, mining platforms, data slicing techniques and clustering techniques are discussed. Ripon Patgiri (2018) presents the taxonomy of Big Data and also present in-depth insight on the Big Data paradigm. Mounica Vennapusa et al., (2019) give the survey on applications and challenges of Machine Learning techniques, advanced learning methods towards Bigdata.

FOCUS OF THE ARTICLE

Machine learning is a field of computer science that try to enable computers with the ability to learn without explicitly programming them. The purpose of this chapter is to provide an analysis of different Machine learning algorithms available for performing big data analytics. The ML algorithms are categorized in three key categories, namely, supervised, unsupervised and semi-supervised ML algorithm. The Big Data Analytics or Big Data Security analytics fully depends on Data Mining, where the Machine Learning techniques are subset of Data Mining (Ripon Patgiri, 2018).

Supervised Learning Algorithms

The supervised learning algorithms are trained with a complete set of data and thus, the supervised learning algorithms are used to predict/forecast.

Figure 1. Supervised Learning Algorithms

Example problems are classification and regression. Example algorithms include: Logistic Regression and the Back Propagation Neural Network.

Unsupervised Learning Algorithms

The unsupervised learning algorithms starts learning from scratch, and therefore, the unsupervised learning algorithms are used for clustering.

Figure 2. Unsupervised Learning Algorithms

Example problems are clustering, dimensionality reduction and association rule learning. Example algorithms include: the Apriori algorithm and K-Means.

Semi-Supervised Learning Algorithms

The semi-supervised learning combines both supervised and unsupervised learning algorithms. The semi-supervised algorithms are trained, and the algorithms also include non-trained learning. Example problems are classification and regression.

Figure 3. Semi-supervised Learning Algorithms

The following brief list identifies the different Machine Learning algorithms when applied in Big Data.

Regression algorithm: It predict output values using input features of the data provided to the system.

Figure 4. Regression Algorithms

Most popular algorithms under it are Linear Regression, Logistic Regression Multivariate Adaptive Regression Splines (MARS) and Locally Estimated Scatter plot Smoothing (LOESS).

Instance based algorithm: It compares new problem instances with instances in training, that are stored in memory.

Figure 5. Instance-based Algorithms

Common algorithms can be k-Nearest Neighbor (kNN), Learning Vector Quantization (LVQ), Self-Organizing Map (SOM) and Locally Weighted Learning (LWL).

Regularization algorithm: It is a process of providing additional information to prevent overfitting or solve an ill-posed problem.

Figure 6. Regularization Algorithms

Algorithms which are common under it are Least Absolute Shrinkage and Selection Operator (LASSO), Least-Angle Regression (LARS), Elastic Net and Ridge Regression.

Decision tree algorithm: It solves the problem using tree representation.

Figure 7. Decision Tree Algorithms

Some popular algorithms are Classification and Regression Tree (CART), C4.5 and C5.0, M5, and Conditional Decision Trees.

Bayesian algorithm: It is based on Bayesian method.

Figure 8. Bayesian Algorithms

Popular algorithms are Naive Bayes, Gaussian Naïve Bayes, Bayesian Network (BN), and Bayesian Belief Network (BBN).

Clustering algorithm: Grouping of data points based on similar features.

Figure 9. Clustering Algorithms

Some popular algorithms are KMeans, K-Medians, and Hierarchical Clustering.

Association Rule Learning Algorithms: It is used to discover relationship between data points.

Figure 10. Association Rule Learning Algorithms

Some common algorithms under it are Apriori algorithm, and Eclat algorithm.

Artificial Neural Network Algorithms: It is based on working of biological neural networks.

Figure 11. Artificial Neural Network Algorithms

Example of some popular algorithms are Back-Propagation Neural Network (BPNN), Perceptron, and Radial Basis Function Network (RBFN).

Deep Learning Algorithms: It uses unsupervised learning to set each level of hierarchy of features using features discovered at previous level.

Figure 12. Deep Learning Algorithms

It has some popular algorithms such as Deep Boltzmann Machine (DBM), Deep Belief Networks (DBN), and Convolution Neural Network (CNN).

Dimensionality Reduction Algorithms: They reduce the number of features by obtaining a set of principal variables.

Figure 13. Dimensionality Reduction Algorithms

Some algorithms commonly under it are Principal Component Analysis (PCA) and Principal Component Regression (PCR), Partial Least Squares Regression (PLSR) and Linear Discriminant Analysis (LDA), Mixture Discriminant Analysis (MDA) and Quadratic Discriminant Analysis (QDA) and Flexible Discriminant Analysis (FDA).

Ensemble Algorithms: It combines multiple learning algorithms to obtain better predictive performance.

Figure 14. Ensemble Algorithms

Some well known algorithms are Random Forest, Gradient Boosted Regression Trees (GBRT), and Gradient Boosting Machines (GBM).

SOLUTIONS AND RECOMMENDATIONS

Some articles authored by IT specialists suggested practical computer science solutions, namely the development of discrimination-aware methods to be applied during the development of the algorithmic models. These techniques include: pre-processing methods that involve the sanitization or distortion of the training data set to remove possible bias in order to prevent the new model from learning discriminatory behaviours (e.g. (Hajian S et al., 2014 and Kamiran F et al., 2013); in-processing techniques that provide for the modification of the learning algorithm through the application of regularization to probabilistic discriminative models (Kamiran F et al., 2013) such as the inclusion of sensitive attributes to avoid discriminatory predictions (Pope DG et al., 2011 and Zliobaite I et al., 2016) or the addition of randomness to avoid overfitting or hidden model bias (Kroll JA et al., 2017); post-processing methods that involve the auditing of the extracted data mining models for discriminative patterns and eventually their sanitization (Hajian S et al., 2015). Practical suggestions to reinforce transparency in data mining include the development of interpretable algorithms that will give explanations on the logical steps behind a certain classification (Kroll JA et al., 2017 and Schermer BW, 2011), and the creation of transparent models that will allow individuals to see in advance how their behavior and choices will be interpreted by the algorithm or the infrastructure (Citron DK et al., 2014 and Hildebrandt M et al., 2010).

FUTURE RESEARCH DIRECTIONS

This Chapter reviews about the various big data mining algorithms. To support big data mining, high-performance computing platforms are required. It is understood that interestingness of discovered patterns, developing a global unifying theory, building efficient mining platforms or algorithms, privacy preserving, security, trust and data integrity are the major challenging issues in the current big data mining scenario. It is known that big data mining is an emerging trend in all science and engineering domains and also a promising research area. In spite of the limited work done on big data mining so far, it is believed that much work is required to overcome its challenges related to the above mentioned issues. (Sherin A et al., 2014)

CONCLUSION

Big data is gaining huge significance in the current scenario and consequently, big data mining emerged as an innovative and potential research area. Many algorithms were defined earlier in the analysis of large data set. Organizations often face teething troubles with respect to creating, managing, and manipulating the rapid influx of information in large datasets. Given the increase in data volume, data sources have increased in terms of size and variety. Data are also generated in different formats (unstructured and/or semi structured), which adversely affect data analysis, management, and storage. This variation in data is accompanied by complexity and the development of additional means of data acquisition. The extraction of valuable data from large influx of information is a critical issue in Big Data. Qualifying and validating all of the items in Big Data are impractical; hence, new algorithms must be developed.

KEY TERMS AND DEFINITIONS

Association Rule Learning Algorithms: It is used to discover relationship between data points.

Clustering Algorithm: Grouping of data points based on similar features.

Data Mining: Data mining is widely used in fields such as science, engineering, medicine, and business.

Decision Tree Algorithm: It solves the problem using tree representation.

Deep Learning Algorithms: It uses unsupervised learning to set each level of hierarchy of features using features discovered at previous level.

Ensemble Algorithms: It combines multiple learning algorithms to obtain better predictive performance.

Regression Algorithm: It predict output values using input features of the data provided to the system.

Semi-Supervised Learning Algorithms: The semi-supervised learning combines both supervised and unsupervised learning algorithms.

Supervised Learning Algorithms: The supervised learning algorithms are trained with a complete set of data and thus, the supervised learning algorithms are used to predict/forecast.

Unsupervised Learning Algorithms: The unsupervised learning algorithms starts learning from scratch, and therefore, the unsupervised learning algorithms are used for clustering.

Graph Database Management Systems: The Past, the Present, and the Future

INTRODUCTION

Nowadays, the increased amount and complexity of connected data stimulated by the appearance of social networks has shed a new light on the importance of managing such data, especially handling information about the connections. The most natural way of representing connected data is to represent them as nodes connected with relationships forming a graph. The concepts of graph theory have been used in many occasions to handle connected data in databases over the years.

The idea of storing data as a set of nodes and edges comprising a graph was implemented in various forms in data models used in the past. The network data model, developed in late 1960s, can be considered as the first data model, which most accurately incorporated this idea. However, it was not long before the relational data model appeared, and took over the entire database market for years, which it dominates even nowadays.

Even though several solutions have been introduced, which can be used to store graph-like data in available relational database management systems (RDBMSs), such as Oracle Graph or MariaDB OQ-Graph, NoSQL graph databases are considered to be the most efficient solution for storing such data, since the idea of storing highly connected data is their primary goal and purpose.

The possibilities of using graph databases in various application domains continue to grow. For instance, the most popular graph databases are Facebook Social Graph developed by Facebook to view connections between friends, or Amazon's graph-based recommendation system (Amazon Neptune service). Sieger discusses the possibilities of introducing concepts of graph databases to modern businesses, and how graph databases could be used for Supply Chain Management or finding deeper connections between patients with similar diseases (Sieger, 2016). Moreover, according to D. Woods, due to their ability to efficiently gain insight into connections between pieces of information, graph databases play (and will play) an important role in transforming modern businesses to data-driven organizations, which make use of their data through the concept of Master Data Management (Woods, 2015).

Since their beginnings, there have been many graph database management systems (GDBMSs) available on the database market (e.g., Neo4j, TitanDB, AllegroGraph, FlockDB, InfiniteGraph, etc.). Recently, new emerging trends can be observed on the GDBMS market; aside from Neo4j, which is still the most popular and constantly developed GDBMS, other „native“ GDBMSs are starting to be replaced and „outgrown“ by multi-model databases, such as OrientDB, ArangoDB, etc.

The aforementioned trends and solutions indicate that it is worth exploring how graph-like data has been stored and manipulated over the years in various data storage solutions, and which current data storage options are available to store and manipulate such data.

DOI: 10.4018/978-1-7998-3479-3.ch053

Therefore, the objective of this article is to give a timeline overview of developed graph data storage solutions in order to gain insight into past, present and future trends of GDBMSs. Additionally, throughout this article, the most influential factors and reasons for changes in trends in GDBMSs' usage will be explored and analyzed.

BACKGROUND

In general, there are various definitions of a graph database; De Virgilio et al. defined graph database as a “multigraph $g=(N,E)$, where every node $n \in N$ is associated with a set of pairs $\langle \text{key}, \text{value} \rangle$, and every edge $e \in E$ is associated with a label” (De Virgilio, Maccioni, & Torlone, 2013), whereas He and Singh defined graph database as a set of graphs $D=\{G_1, G_2, \dots, G_m\}$, where graph G is denoted by (V, E) , V being a set of all vertices, and E being a set of all edges (He & Singh, 2006).

Graph database model can be defined as a data model, in which “data structures for the schema and instances are modeled as graphs or their generalizations, and data manipulation is expressed by graph-oriented operations and type constructors” (Angles & Gutierrez, 2008). Graph database model consists of three components (Angles & Gutierrez, 2008):

- structural component (graph data structures),
- operational component (graph-oriented operators), and
- integrity component (integrity constraints).

Nowadays, the most commonly used graph database model is the property graph data model (Figure 1), which can be defined as a “multigraph data structure, in which graph elements (vertices and edges) can have properties/attributes” (Ciglan, Averbuch, & Hluchy, 2012).

Data stored in a graph database can be queried by using a graph query language, which can provide support for different graph-related operations, such as graph union/intersection/difference, graph filtering, adjacency, path traversal, or pattern matching queries (Kaplan, Abdulla, Brugger, & Kohn, 2007).

Figure 1. Sample property graph data model (Neo4j Inc., 2018)

Hence, a graph database management system (GDBMS) is “a database management system with CRUD (Create, Read, Update, Delete) operations based on property graph data model” (Saha, 2017).

GRAPH DATABASE MANAGEMENT SYSTEMS DEVELOPMENT OVERVIEW

To achieve the objective of this article, i.e., give an overview of past, current and future research trends in the field of graph databases and GDBMSs, a literature review has been conducted to identify relevant published research papers. The analyzed papers were then divided based on their research topic into three categories:

- papers discussing GDBMSs in the past (before 2009),
- papers and topics discussing GDBMSs in the present (2009 – current), and
- papers and topics discussing potential future research trends related to GDBMSs.

Graph Database Management Systems in the Past

The story of storing both entities and their relationships in the database began with hierarchical and network database models, which appeared in 1960s. Between these two, the network database model can be considered as the first “complete” solution for storing connected data in the database at that time due to its ability to store complex and many-to-many relationships (as opposed to only one-to-many relationships available in the hierarchical database model), i.e., in the network database model, a child record can be connected to multiple parent records and vice versa (Maleković, Rabuzin, & Šestak, 2016). The network database model is represented as an inverted tree consisting of records connected with owner-member relationships, which can be implemented as pointers or indexes on the physical level (Harrington, 2002). The most popular network database model used at that time was the one developed in 1971 by CODASYL DBTG¹ (sample model shown in Figure 2), which was then implemented in various DBMSs, and is still used nowadays (Hainaut, 2009).

Figure 2. Sample network data model (Khalil, 2018)

Even though network databases were soon “replaced” by relational databases, nowadays it is still possible to explore their characteristics through Raima Database Manager (RDM) solution developed by Raima Inc., which provides a query language, tools and other utilities to implement a network database model (Maleković et al., 2016).

Graph Database Management Systems in the Present

Research papers published from 2009 until now indicate that graph databases and GDBMSs face challenges common to other database technologies as well.

One of the most important challenges nowadays is storing the growing amount and size of data generated by different applications and businesses. Even though graph databases show good performance in handling such data, it is still necessary to explore how new and trending concepts, mechanisms and technologies can be used to improve their performance and stability in storing and retrieving necessary data in the shortest amount of time (e.g., data compression). The era of cloud solutions and distributed environment represents an additional challenge in scaling and partitioning graph databases without major performance losses.

On a conceptual level, the issue of graph database modeling and introducing some form of graph database schema (less strict than in relational databases) has proved to be of great importance to be standardized and constantly explored, since a correct and accurate graph database model can significantly influence the performance of future graph queries, changes in database structure, etc.

Another great issue quite popular in the research community is the lack of a standardized graph query language. Nowadays, it happens quite often that each modern GDBMS (e.g., Neo4j, TinkerGraph, InfiniteGraph) uses different approaches and query languages to query the underlying graph database, which can be seen in comparison of selected GDBMSs (AllegroGraph, JanusGraph, Neo4j and TinkerGraph) in Table 1. When it comes to graph query languages, there are two important aspects, which need to be considered, which make a query language effective and preferable among its users:

1. the language syntax must remain as simple and understandable as possible for different categories of users ranging from beginners to professionals and domain experts, and
2. the query formulation process must be simplified, but also ensure that the query performance is efficient, effective and stable.

Table 1. Comparison of selected graph DBMSs (Adapted from <https://db-engines.com/en/>)

	AllegroGraph	JanusGraph (former Titan)	Neo4j	TinkerGraph
Primary database model	Graph DBMS RDF store	Graph DBMS	Graph DBMS	Graph DBMS
Data scheme	yes (RDF schema)	yes	schema-free and schema-optional	schema-free
Access methods	RESTful HTTP API SPARQL query language	Java API Tinkerpop computing framework	Cypher query language Java API Neo4j Object Graph Mapping library RESTful HTTP API	Tinkerpop 3 graph computing framework
Transaction concepts	ACID ²	ACID	ACID	no
Foreign keys	no	yes (implemented as relationships in graphs)	yes (implemented as relationships in graphs)	no
License	commercial	open-source	open-source	open-source

The increasing popularity of graph databases (and NoSQL technologies in general) also presents a challenge to convert existing relational database solutions to graph databases to ensure an easy and issue-free transition between the two paradigms. Additionally, in their beginnings, the primary application domain of graph databases and GDBMSs were social networks, fraud detection and recommendation systems. Over the years, the achieved research progress and new GDBMS features have expanded this domain in order to keep up with current technology trends.

Finally, there is a growing tendency to use graph databases for analytical purposes (not only operational) as well, which has led to developing various systems, modules and tools for fast data analysis, as well as different algorithms and methods for data mining in graph databases. Furthermore, the support for implementing RDF (Resource Description Framework) data model in GDBMSs offers an opportunity to handling semantics of data stored in this graph database.

The aforementioned issues and challenges are continually being solved through novel GDBMS architectures, algorithms, frameworks, methods, etc., introduced in both theory and practice, which will be discussed in detail in the following section.

SOLUTIONS AND RECOMMENDATIONS

The topics of graph database modeling and graph query languages have been studied in several research papers. In (Angles et al., 2017), the authors discuss edge-labelled and property graphs as two popular graph data models, different graph querying approaches (graph patterns and navigational expressions), and outline the importance of formalization of graph query languages, such as Cypher, Gremlin or SPARQL. Graph database models and query languages are also discussed in (Soussi, Aufaure, & Baazaoui, 2011).

The process of converting existing relational database solutions to the context of graph databases has been addressed in (Roy-Hubara, Rokach, Shapira, & Shoval, 2017), in which the authors investigate how to create a graph database schema based on an entity-relationship diagram of the application domain. Also, in (Park, Shankar, Park, & Ghosh, 2014), the authors propose a “3NF equivalent graph” transformation to be used for migrating healthcare data from a relational to a graph database.

Modern GDBMSs, such as Neo4j, offer a wide range of features for storing and querying data from the underlying database. However, topics covered in the research community (e.g., graph data partitioning, novel querying approaches, algorithms for query optimization) are often covered only in theory, i.e., rarely implemented in GDBMSs. The most popular graph query language is Cypher, mostly due to its easy-to-learn syntax and pattern matching approach to query processing. According to many users, the biggest drawback for using graph databases is the lack of a standardized query language, which is currently being solved through a so-called “openCypher” project, i.e., an initiative for transforming Cypher language into a standardized graph query language.

Storing billions of nodes and edges is not possible without using some kind of compression techniques and methods. In (Sutrisna, Saleh, & Gozali, 2015), the authors use Graph Algorithm Clustering to compress the graph database, and to produce a lossless and compressed database.

Furthermore, the process of retrieving data from graph database can improve in various segments by using different approaches. S. Das et al. propose a query optimizer for graph databases in (Das, Goyal, & Chakravarthy, 2016). In (Castelltort & Laurent, 2016), the authors discuss how to use in-memory architectures to extract graph database summaries to speed up the graph database querying process. In (Spyropoulos, Vasilakopoulou, & Kotidis, 2016), the authors present “Digree, an experimental middle-ware system that can execute graph pattern matching queries over databases hosting voluminous graph

datasets”. In (Zhang, Gao, Wu, Li, & Gao, 2011), the authors propose a new approach for processing supergraph queries, and a new algorithm for testing subgraph isomorphisms. Another interesting challenge is to find answers to queries over inconsistent graph databases, which is addressed by Barceló and Fontaine in (Barceló & Fontaine, 2017).

In (Yung & Chang, 2017), the authors explore reachability queries, and propose a “How-to-Reach” query to be used when a user does not know, or is unsure how to reach from source to the destination. Similar ideas are presented in (Vasilyeva, Thiele, Bornhövd, & Lehner, 2016), in which the authors propose “Why Empty?” and “Why So Many?” queries, which should explain why a result is empty, or contains too many rows. Queries returning empty answers are also discussed in (Vasilyeva, Thiele, Bornhoevd, & Lehner, 2014); the authors propose the use of top-k differential queries, which should deliver the missing parts of the query graph, so that users have insight into what was missing in the query, and why the query returned no result.

On low-level graph query processing, various algorithms and methods have been introduced to improve the subgraph isomorphism and similarity search processes, which can result in improved query performance (Chodpathumwan, Aleyasen, Termehchy, & Sun, 2016; Kiran & Sivadasan, 2015; Luo, Guan, & Zhou, 2011; Y. Yuan, Wang, Chen, & Wang, 2015).

In addition to query execution performance improvements, several approaches and frameworks have been introduced to simplify the query construction process for end users, such as query auto-completion (Yi, Choi, Bhowmick, & Xu, 2017) and graph exploration (Didimo, Giacche, & Montecchiani, 2015).

Additionally, indexing is always an interesting choice to consider when database performance needs to be improved. In (Azaouzi & Ben Romdhane, 2017), the authors propose the so-called Structural Graph Indexing, called GIRAS, “an indexing feature based on Rare subGraphs (RGs)”, which can be used to decrease the size of the candidate answer set when querying the database. In (D. Yuan & Mitra, 2013), the authors propose a graph index called Lindex, which indexes subgraphs contained within the graph database. In (Jarrar & Deik, 2015), the authors propose a Graph Signature Index suitable for indexing and querying large data graphs. In (Sakr & Al-Naymat, 2010), the authors present different techniques for indexing and querying graph databases.

Another way of improving graph database querying is to use data partitioning. However, graph data partitioning still represents a challenging issue, and only several research papers have been published, which address the issue in question (Barguñó, Muntés-Mulero, Dominguez-Sal, & Valduriez, 2011; Ben Ammar, 2016). Graph data partitioning also represents a basis for building distributed graph databases.

Integrity constraints in graph databases and graph database schema are explored by J. Pokorný et al. in (Pokorný, Valenta, & Kovačič, 2017), in which the authors discuss the level of integrity constraints and schema support in Neo4j GDBMS. In recent years, various graph query languages have been proposed in addition to Cypher, Gremlin and SPARQL graph query languages, which introduce improvements in graph database querying in different segments; a detailed overview was published by P. Wood in (Wood, 2012). For instance, in (Chavarria-Miranda, Castellana, Morari, Haglin, & Feo, 2016), the authors propose a new language called GraQL for attributed graph databases, whereas in (He & Singh, 2008), the authors propose GraphQL query language based on the concept of graph patterns and graphs as the basic unit of information. Additionally, transaction support in graph databases is discussed in (Koloniari & Pitoura, 2016).

An interesting change in GDBMS usage can be noticed in GDBMS market share. Figure 1 shows the ranking of currently top 10 mostly used GDBMSs and their underlying database model according to DB-Engines knowledge base. Based on the figure, it can be observed that among listed DBMSs only two of them are based “purely” on a graph database model (Neo4j and Giraph), whereas the rest

of DBMSs support other database models as well (e.g., documents, key-value pairs, etc.). Therefore, “pure” GDBMSs are slowly being “overtaken” by multi-model DBMSs, which can store data in other database models in addition to graph database model as well.

Figure 3. Top 10 GDBMS ranking (DB-Engines, 2018)

Rank			DBMS	Database Model	Score		
Jun 2018	May 2018	Jun 2017			Jun 2018	May 2018	Jun 2017
1.	1.	1.	Neo4j +	Graph DBMS	41.97	+1.39	+4.10
2.	2.	2.	Microsoft Azure Cosmos DB +	Multi-model ?	19.20	+1.66	+12.82
3.	3.		Datastax Enterprise +	Multi-model ?	7.25	-0.12	
4.	4.	↓ 3.	OrientDB +	Multi-model ?	5.35	+0.10	-0.46
5.	5.	5.	ArangoDB	Multi-model ?	3.52	-0.18	+0.44
6.	6.	6.	Virtuoso	Multi-model ?	1.78	-0.01	-0.22
7.	7.	7.	Giraph	Graph DBMS	0.97	-0.01	-0.08
8.	8.		Amazon Neptune	Multi-model ?	0.67	-0.03	
9.	9.	↓ 8.	AllegroGraph +	Multi-model ?	0.55	-0.03	-0.05
10.	10.	↓ 9.	Stardog	Multi-model ?	0.50	-0.01	-0.04

Currently, many published research papers focus on expanding the applicability of graph database technology to various application domains, such as genetics and medicine, networking, tourism, power systems, etc., which proves that the technology will continue to spread, and that the popularity of graph databases will continually grow in years to come.

FUTURE RESEARCH DIRECTIONS

Even though the popularity of graph databases is constantly increasing, there are still topics and issues that need to be solved. Nowadays, the increasing amount of papers and researched topics indicate several research and development trends in the field of GDBMSs and graph databases, such as semantic graph databases, graph mining, graph data warehouses and graph cubes (Liu & Vitolo, 2013), graph query language standardization initiatives, etc.

For instance, in (Kostylev, Reutter, & Vrgoč, 2016), the authors discuss how to use XPath query language over graphs, whereas in (Lian, Chen, & Wang, 2016), the authors discuss different methods for “quality-aware subgraph matching over inconsistent probabilistic RDF graphs (QA-gMatch)”, which goal is to retrieve subgraphs isomorphic to a given query graph from inconsistent probabilistic RDF graphs.

Additionally, there has been a lot of research focusing on using graph concepts and graph databases for data mining purposes, e.g., frequent subgraph mining (Wang et al., 2016), but also for object, image (Lampoltshammer & Wiegand, 2015) and handwriting recognition (Stauffer, Fischer, & Riesen, 2016).

According to (Green, 2018), a new initiative has been undertaken recently to develop an industry-standardized property graph query language called GQL (Graph Query Language). GQL will combine properties of PGQL (Property Graph Query Language), G-CORE (graph query language used among

researchers) and the openCypher language mentioned in the previous section, and will be used across different GDBMSs (as its counterpart SQL³ in relational DBMSs).

As highlighted in the previous section, current industry trends show, besides Neo4j as the most popular “pure” GDBMS, which is constantly being improved and extended with new features, graph features can also be used in multi-model DBMSs, such as OrientDB or Cosmos DB. Furthermore, the existing relational DBMSs, such as Oracle and Microsoft SQL Server, are starting to extend their support for graph databases as well. This initiative will certainly present an important challenge for Neo4j and other GDBMSs in the future.

CONCLUSION

In this article, an overview of past, current and potential future research and industry trends in the field of GDBMSs and graph databases has been presented. The lack of a standardized graph query language has been identified as currently their major drawback, but research papers published in recent years, as well as current industry initiatives for developing a standardized graph query language (openCypher, GQL) indicate that this problem will soon be resolved. For years, the most widely used GDBMS has been Neo4j. However, recent trends show that other existing DBMSs, which do not support graph data model natively, are continually introducing new features for managing graph-like data (e.g., Oracle). Therefore, it can be presumed that, in the future, Neo4j will be continually developed as a “pure” GDBMS, while other DBMSs will work on partially supporting graph data model.

KEY TERMS AND DEFINITIONS

Graph Data Partitioning: The process of logically partitioning data stored in a graph database into segments, which can then be stored in different locations.

Graph Data Warehouse: A system used for data analysis, in which a data source is a graph database.

Graph Database Model: A conceptual representation of graph-like data in the form of graph nodes and edges.

Graph Mining: The process of discovering patterns in data stored in a graph database through complex data analysis.

Graph Pattern Matching: The process of finding all subgraphs matching a given graph query pattern in the original graph.

Graph Query Processing: The process of transforming a query written using a given graph query language syntax into a low-level query execution plan.

“Pure” Graph Database Management System: A system, which supports CRUD (Create, Read, Update, Delete) operations on graph data represented in the graph database model.

ENDNOTES

INTRODUCTION

In recent decades, the relational model has been the mechanism of persistence of information most used in the computer applications. It provides a mature and stable model to represent the data, and also offers a widely used standard query and manipulation (SQL) language.

1. However, the appearance of the “Big Data” phenomenon has meant a change in the storage and information processing needs. This new context is characterized by: a) enormous amounts of information are available in heterogeneous formats and types, b) information must be processed almost in real time, and c) data models evolve periodically.
2. This requires a greater processing capacity, greater flexibility in terms of the types of information data that can be stored and greater flexibility in the data models that facilitate their adaptation.
3. Relational databases have limitations to respond to these needs in an optimal way given that:
 - The solution to achieve more processing capacity is to use more powerful machines (vertical scaling). It is not economically advantageous.
 - The evolution of the data models implies a modification of the database schemas. This causes problems of maintenance and consistency of previously stored information.
 - The storage of heterogeneous and complex data requires the transformation of information in order to store complex data in basic data types (the only ones that manage relational databases).

For these reasons, some companies such as Google or Amazon decided to create new database models (different from the relational model) that solve the needs raised in the context of Big Data without the limitations of relational databases. These new models are the origin of the so-called NonSQL Databases.

Currently, NonSQL databases have been constituted as an alternative mechanism to the relational model and its use is widely extended.

The main objective of this chapter’s proposal is to introduce the NonSQL databases. Specifically:

- To show the processing and persistence needs of information in the Big Data.
- To describe the main characteristics and the conceptual basis of the NoSQL databases.
- To show how the NoSQL databases solve the needs raised in the Big Data
- To describe the main families of NoSQL databases and the data models on which they are based.

The structure of the chapter is as follows. Section 1 describes the storage needs that appear in the Big Data. Section 2 presents the limitations of the databases to cover the needs of Big Data. Next, the

DOI: 10.4018/978-1-7998-3479-3.ch054

NoSQL databases and their main characteristics are introduced. In the following section, persistence and distribution models are discussed. Next, the CAP theorem is presented. Finally, the trends in the NoSQL world are discussed, and a set of conclusions is established.

BACKGROUND

Big Data is a technological challenge that arises due to the confluence of two phenomena (Chen et al, 2014). On the one hand, there is a rapid increase in the storage capacity of the hardware and a reduction in its cost (in the 1980s it was possible to handle data sizes of 0.02 EB, in 2013 they handled sizes of 4.4 ZB, and in 2020 it is estimated that it will be possible to handle sizes of 44 ZB). And on the other hand, some companies and institutions begin to generate large amounts of data in a very fast way (for example, Google generates around 20 PB of data daily and Facebook 500 TB). The possibility of storing this data by having storage with sufficient capacity makes companies start to exploit the stored data for economic or strategic purposes, and to obtain benefits from the results of the analyzes. Thus, an infinite loop begins in which more and more data are generated, which forces us to develop media with greater storage capacity. When initial storage needs have been met, they are no longer able to meet current needs (since the amounts of data generated increase exponentially), which makes it necessary to create new storage media with greater capacity.

Big Data affects different technical aspects related to the storage and processing of information (Khan et al, 2014):

- The types of data that need to be managed are very different in nature, they require the storage of data that can be structured, semi-structured or simply without structure.
- The quantities of data that need to be processed are increasing, so that the necessary processing capacity also increases very rapidly. In this sense, observe that another requirement is the need for the processing to be done almost in real time.
- The data sources that need to be processed can change at any time, which is why we need sufficiently flexible information organization schemes that adapt to different information structures.
- The new context in terms of data types and number of data, makes it necessary to develop new techniques for analyzing information and interpreting the results thereof.

Thus, the technological areas affected by these new needs are varied. However, this chapter will focus on changes in information storage systems. Next, it will be analyzed the limitations of the relationship databases to cover the new needs of Big Data in terms of storage of information.

During the last decades, the relational model has been the most widespread way of carrying out the persistence of information. However, it presents important limitations to cover the main needs arising in the Big Data (Li et al, 2013). Then, each of them will be analyzed (Jacobs, 2009):

- The problem of the data schema (Zhao et al, 2014). In the relational model, a task prior to the storage of the data consists of creating a schema of the type of information to be stored. In this way, they describe the types of data are admitted. If it necessary to store other types of data then it will have to make changes to the scheme. However, these changes often introduce anomalies in the stored data (for example, in terms of the relational model there will probably be rows with many columns with null values). In this sense, it is said that the information stored in a relational

database is structured because it follows a previously defined scheme. In the field of Big Data, the information that needs to be stored can be very diverse, from structured, semi-structured data or even data without structure. In addition, in general it is not known a priori how the type of data will be. For these reasons, it is not possible to define a fixed structure for the information it must be stored. Thus, the characteristics of the data that needs to be stored in a Big Data environment are incompatible with the need to set a previous scheme of data in the relational model, since its use would make it necessary to make changes in the schema for each new type of data that it would have to store. Besides, this situation would introduce anomalies in the database and the need to do changes in the tables and relationships defined.

- The problem of the difference of data structures (Pokorny, 2015). It is a problem related to the previous one. In the relational model, the data structures used to store information are simple data types such as integers, reals, strings, dates... So in order to store real-world information, it must be decomposed in terms of types of data. simple data. On the other hand, the processing of information from a database is usually done from a program written in some information language. To do this, the data is extracted and stored in the data structures offered in the programming language. These structures are more complex than those managed by a relational database, so it is necessary to make a process of composition of the simple data from the relational model to the complex structures of the programming language. In the same way, when you want to store the information managed in a programming language in a relational database, you must perform the inverse process of decomposing complex structures into simple data. These processes of composition and decomposition suppose a cost in terms of efficiency that can not be ruled out when the amounts of information that are going to have to be transformed are enormous, as it is in the case of Big Data.
- The problem of information processing (Jatana et al, 2012). As noted above, the information processing capabilities required in the Big Data field are changing dynamically in an increasing manner. To increase the processing capacity there are essentially two ways: vertical scaling and horizontal scaling. Vertical scaling involves the acquisition of increasingly powerful machines. Thus, when a situation arises in which the machine that performs the processing is not sufficient for the existing needs, then it is replaced by another more powerful machine. However, horizontal scaling is to achieve the necessary processing capabilities through the collaboration of a set of machines with less processing power than the required jointly collaborate to meet the required processing needs (this set of collaborating machines is called cluster of machines). From the economic point of view, vertical scaling is not a good solution because the processing capacity is directly proportional to the cost of the machine (more capacity means higher cost). Thus, if it is necessary to increase the processing capacity it would be necessary to buy a new machine with greater capabilities and therefore with a significant economic cost. However, in horizontal scaling, when using less powerful machines, the total cost of the necessary machines will be lower. In addition, if it is necessary to increase the processing capacity it would be enough to buy new machines with lower capabilities (and therefore with a lower economic cost compared to vertical scaling) that would be added to the current machine cluster. Therefore, the problem of the increasing need for processing capacity is solved in an optimal way using horizontal scaling. However, this solution is incompatible with the use of relational databases, since they are designed to run in centralized environments on a single machine, and not to run on a set of machines where processing is distributed. The distributed execution of a relational database introduces problems in aspects such as performing operations of type join or on the distribution of data rows of a table.

SOLUTIONS AND RECOMMENDATIONS

Due to the limitations of the relational model (discussed in the previous section) to cover the storage needs of Big Data, some companies such as Google (Big Tables) or Amazon (Dynamo) developed new alternative persistence systems (Kalid et al, 2017) to the relational model (Chen et al, 2014). A common feature was its ability to manage and carry out the processing of huge amounts of data in distributed environments. These alternative systems are the origin of the so-called NoSQL Databases (No SQL), which served as a starting point for the development of other alternative systems. It is complex to define a classification of the different types of NoSQL Databases (Gessert et al, 2017), since many of them share characteristics. However, there is a first level classification that defines several families (Nayak, 2013):

- Key-value data bases such as Riak, Redis, Dynamo or Voldemort (Kalid et al, 2017)
- Document-oriented databases such as MongoDB or CouchDB (Jose et al, 2017)
- Databases based on columns such as Cassandra, Hypertable, HBase or SimpleDB
- Databases of graphs such as Neo4J or Infinite Graph.

There is a set of characteristics shared by most of the NoSQL databases (Han et al, 2011):

- 1) One of the most important features is that they do not use SQL as a query language. In general, all of them have a query language to be able to manage and consult the information they store, but their syntax and the type of possible operations are different from the SQL language of the relational databases. However, there is a case in which the query language has a certain similarity with SQL, such as the CQL language of the Cassandra database (Hsieh et al, 2017)
- 2) In most cases these are open source projects.
- 3) Another feature that most of these types of databases fulfill is that they have been designed to run in environments distributed over a cluster of machines. This feature has influenced the underlying data models used to store the information or solutions used to address the consistency problem. However, some models do not fulfill this characteristic, as is the case of graph-oriented databases that run in centralized environments.
- 4) They do not use a fixed information scheme, so that information can be added freely without being subject to any structure (Gupta et al, 2017). This feature has several implications with respect to the limitations of the relational databases discussed above. On the one hand, the problem of having to previously fix the types of data that can be stored is solved, any type of data compatible with the data model of the database used can be stored. And on the other hand the problem of the cost of the process of composition and decomposition of the data is solved, given that the data structures used in this type of databases are similar to those used in the programming languages. However, two aspects of this flexibility in terms of information schemes must be observed. On the one hand, some tasks performed by database management systems such as correcting the data entered, how to store and retrieve information in the most efficient way, or checking the consistency of the data that are manipulated by the applications that access the database, now they will have to be carried out directly by the programmers (Branch et al, 2017). And on the other hand there is the problem of knowing information about stored data such as the type of data, names of the information fields... In this sense, although there is no explicit schema in the database, if there is an implicit schema in the programs that manage the database. Thus, some aspects such as where each type of data is stored, what are the data formats that can be used, how is the structure of the database..., are described in

the programs that access it. This is a weakness, for example when changes occur in the database, since these changes will have to be transferred to the programs.

With regard to distribution models, two distribution models can be found: replication and sharding (Hecht et al, 2011). Replication consists of having copies of the data managed by the distributed database on multiple machines in the cluster. Within this model, you can find some two variants: the Master-Slave model and the Peer-to-Peer model. The first model is characterized because there is a machine called “Master” that stores the reference copy of the system. Thus, all the deeds and modifications of the data are made on this copy. The rest of the machines called “Slaves” keep copies of the Master data, and they support the data readings that are made on the system. Likewise, the slave machines must be kept synchronized with the Master machine so that any change that occurs in the copying of reference data is reflected in the copies of the slave machines. The second model is characterized in that all machines play the same role, and can receive both readings and data writes, which requires synchronization of all the machines in the cluster every so often in order to maintain the consistency of the data. The advantage of the first model is the reduction of inconsistencies in the information that is updated (since it is done in a single machine) while the second model has the advantage of reducing the overload of data writing and modification operations, given that it is done on any of the machines in the cluster.

On the other hand, sharding (Pokorny, 2013) consists of distributing the managed data in different machines, so that each of them will have a subset of the totality of managed data. This model has advantages in aspects such as the possibility of managing large amounts of data, the possibility of processing a greater number of read and write operations, presenting greater availability before failure situations in the communications network,... However, the cost associated with the complexity of the system is the main disadvantage

These are two orthogonal models, and are generally used in combination. A replicated and distributed system has the advantages of guaranteeing access to data (even if one machine fails, you can always access another one that maintains a copy of the data) and make it easier to scale up the processing capacity when the data increased (Just it is necessary add more machines to the cluster to distribute the new data).

Regarding the consistency of the information (Stonebraker, 2012), it should be noted that one of the characteristics of the NoSQL databases is that this aspect is no longer a task of the database management system, and becomes a task of the programmer. In this sense, the ACID model of transactions is not guaranteed in this context. Thus, different types of conflicts can be found regarding the consistency of the information: writing-writing conflict, reading-writing conflict and reading conflict. The first case occurs when you try to perform two updates of the information at the same time. In this case, the problem of the order in which the updates are made is raised since inevitably one of them will overwrite the other. The second type of conflict occurs when you try to perform a reading at the same time you try to write on the same data. Depending on the order in which the operations are carried out, an inconsistency in the read data may occur. The third type of conflict occurs in systems where data replication has been used. In these systems, there is a period of time called “window of inconsistency” during which some slave machines are in an inconsistent state with respect to the Master machine where the update occurred (Corbellini et al, 2017). In this situation, if a reading occurs on a slave machine, the information read may be inconsistent with respect to the updated information. Observe that it is possible to design a system that avoids inconsistencies, but will have the cost of sacrificing other characteristics. Likewise, we must bear in mind that each domain has a different tolerance to inconsistency (it is not the same to allow an inconsistency in an online newspaper than in a web page that is dedicated to the purchase and

sale of shares of the Stock Exchange), and that different levels of consistency could be used based on the type of information that is managed or the type of update to be made.

There is a theorem called “CAP Theorem” applicable to distributed systems that run in a cluster of machines such as the NoSQL databases (Li et al, 2013). It establishes that given a distributed system if one considers the properties of consistency, availability (access to a machine of a cluster to read and write data) and tolerance to partitioning (to support breaks of communication between the elements of the system), then it is only possible guarantee 2 of them at a time. Thus, the theorem states that a system can suffer partitions and consistency must be compensated to achieve availability. In this sense, the system will not be completely consistent or available, but it will have a reasonable combination (depending on the domain it is possible to maintain certain inconsistencies during a certain period of time allowing increasing the availability and performance of the system).

FUTURE RESEARCH DIRECTIONS

NoSQL databases have become an alternative to the widely accepted relational model. There are two trends currently regarding its use (Davoudian et al, 2018):

- a. Polyglot persistence (Assunção et al, 2015). NoSQL databases should not be used in all cases of data persistence. In many situations, the information storage needs require mixed solutions where a relational database is combined that will be in charge of managing structured data with a NoSQL database that will be responsible for managing semi-structured or unstructured data (Haseeb et al, 2017). In these cases, the communication between both systems will be done through a web services API that hides the way to access and retrieve the information. The advantages of these solutions is the efficient adaptation to the needs of each type of information that must be managed by the system. It also allows to scale and adapt each type of database in a transparent manner without affecting the rest of the solutions.
- b. The NewSQL databases (Kumar, 2014). Another trend in the NoSQL world are the so-called NewSQL databases. It is a set of tools (Stonebraker, 2010) that maintain both the use of the relational model, the SQL query language to manage the stored data and the ACID model but achieving the same scalable performance as the NoSQL databases to process reading transactions -writing. A common feature (Paylo et al, 2016) to all of them is that they have been designed to run in a distributed cluster, so that each node has a subset of the managed data. Regarding the processing of queries, there are different approaches. One of the most widespread techniques (Niazi et al, 2017) is to perform transactions and queries to the cluster machines that contain the necessary data, so that the queries are divided into fragments.

CONCLUSION

In this chapter it has presented a new type of databases called NoSQL that emerge as an alternative to the relational model. The reasons for its appearance are found in the limitations of the relational databases to cover the persistence needs that appear in the Big Data (essentially the need to process data of any kind, in huge quantities, in a fast way and in distributed environments). These persistence systems have some common characteristics, such as not using SQL as a query language, not using a fixed schema to

represent the structure of the information they store and, in most cases, running in a cluster of distributed machines. These characteristics have a cost in terms of the consistency of the information since they do not guarantee the ACID properties, and also many of the tasks previously performed by the database management systems in terms of data validation, correction of the information that is stored..., now they must be done by the programmer. Precisely with respect to the consistency of the information, different types of inconsistency arise that must be taken into account in the design of the persistence solutions (and that will depend on the domains in which it will be used): writing-writing inconsistency, reading-writing inconsistency or reading inconsistency. Another aspect that arises in this context are the different ways of distributing the data, which can be done in two different ways: replication and sharding. Each of these solutions has its own characteristics, although generally there is a tendency to implement combined solutions of distributed data replication. Finally, it is mentioned that there are two trends mainly in the NoSQL world: NewSQL databases (Pavlo et al, 2016) and mixed persistence solutions. In the first case, they are databases that maintain the relational model but allow its distributed execution as well as other similar characteristics of the NoSQL databases. And mixed persistence solutions propose using the best solution, whether relational or NoSQL, for each type of data that must be managed by a system.

KEY TERMS AND DEFINITIONS

Big Data: It is a phenomenon that involves a set of tools, technologies and techniques that aim to process huge amounts of data of all types in order to exploit the information contained and obtain some kind of advantage.

Consistency: It refers to the mechanism that ensures that the data that is retrieved from a database is valid and is updated.

NoSQL Database: It is a database that is not designed using the relational model as a basis. It presents, among other features, that it does not use the SQL language as a query language.

Relational Database: It is a database that is designed using the relational model as a basis. Its main characteristic is that it organizes the information using tables as a storage unit. Likewise, it uses SQL as a query language.

Replication: It consists in making a copy of the data in more than one machine of a distributed system in order to guarantee that the data is not lost in the case of the fall of any of the machines.

Scaling: Refers to the way you can increase the processing capacity of a system. There are two types: vertical scaling and horizontal scaling. In the first case, it consists of acquiring a machine with better features than the previous one, while in the second case, it consists of creating a cluster of machines that collaborate with each other, so that the processing powers of all the machines are added.

Sharding: It is an organization of information that consists of distributing data among a set of machines so that machines can define roles such as a machine acting as a server and the rest of customers or that all machines act with the same roles.

SQL Language: It is a declarative language that is used in relational databases to make queries.

Theorem CAP: It is a theorem that establishes a set of properties about the distributed systems with respect to the availability, consistency of the data or the partitioning of the system.

EDRC: An Early Data Lending–Based Real– Time Commit Protocol

INTRODUCTION

The advanced Distributed Database System (DDBS), with the integration of ‘real-time’ attribute to each transaction, makes sure that results are produced within a stipulated deadline while maintaining the consistency. Such systems are broadly studied under the umbrella of the research area named Distributed Real Time Database System (DRTDBS). In simple, they are time constrained DDBSs (Pandey & Shanker, 2018a). In the DRTDBS, the distributed real-time transaction (DRTT) is invoked to perform changes at multiple sites atomically. Here, the correctness of the result depends on two things: logical computation performed, and the time when the result is produced. Even if the result produced is functionally right, it may lead to tragic repercussions, be unusable, or has less value if it is not produced in time (Shanker, Misra, & Sarje, 2001).

Based on the consequences of their deadline misses, DRTTs may be categorized as soft, firm and hard. The soft DRTT is not killed/aborted in case of its deadline miss because the result has some value (obviously degrading) even after the deadline miss. The firm DRTT is killed in case it misses its deadline because its outcome has no value after the deadline miss. In addition, allowing the execution of firm DRTT after its deadline expiry may also lead to deadline expiration of other concurrently executing firm DRTTs requiring access to resources already locked by it. The hard DRTT must be finished before its deadline; otherwise, it may lead to a potentially catastrophic consequence.

Scheduling concurrent execution of DRTTs is extremely complex as the goal of database management algorithms is not only to maintain database consistency but also to ensure that timing constraints are met. Issues such as data conflicts, site failures, communication delays, interaction through the underlying operating system and I/O subsystem are major obstacles in meeting the deadlines of concurrently executing DRTTs (Shanker U., 2008). Among all these, the data conflict problem is a key factor that adversely affects system performance; it can be categorized as Execute-Execute Conflict and Execute-Commit Conflict. The Execute-Execute conflict may occur amongst executing transactions. A considerable research investigation has been carried out to resolve this conflict. For detailed knowledge about the Execute-Execute conflict and strategies proposed for its resolution, the readers may go through (Shanker, Misra, & Sarje, 2008). The Execute-Commit conflict may occur between executing and committing transactions. It occurs only if one of the transactions involved in data conflict is in a PREPARED state.

DOI: 10.4018/978-1-7998-3479-3.ch055

The real-time concurrency control protocol resolves execute-execute conflict while the real-time commit protocol, an optimistic implementation of 2-Phase Commit (2PC) protocol with relaxed ACID property, resolves execute-commit conflict.

To overcome execute-commit conflicts, the lender-borrower approach is commonly used in next generation commit protocols — which are not only of optimistic nature, but also intended to satisfy real-time constraints. Such real-time commit protocols permit prepared lender cohorts to lend their modified and uncommitted data items to executing borrower cohorts in case of occurrence of Execute-Commit conflict between them. This reduces data inaccessibility. Thus, they improve DRTDBS performance. They, however, usually do not permit the borrower cohort to send WORKDONE/PREPARED message, and thus, increase the borrowing transactions' commit time. Hence, designing efficient real-time commit protocol is a vital issue as it largely affects the DRTDBS performance.

BACKGROUND

The research on developing an efficient real-time variant of the classical 2PC is still an open question in the study of the DRTDBS (Pandey & Shanker, 2016). Ramesh Gupta et al. first proposed a real-time variant of classical 2PC protocol named OPT (Gupta, Haritsa, Ramamritham, & Seshadri, 1996); this protocol is specifically designed to fulfill the consistency and deadline requirements of the DRTDBS by reducing the negative impact of Execute-Commit conflict and inherent priority inversion problem. The OPT protocol permits a high priority cohort to borrow/access the uncommitted data item(s) held by prepared low priority cohort. Such lending by a prepared cohort creates a dependency between conflicting DRTTs. The fate of borrower DRTT depends on the final outcomes of DRTTs from whom it had borrowed the data items — if final outcomes of all the lender DRTTs are 'commit', then only the borrower DRTT can start its commit processing. Thus, the OPT makes the borrower to be blocked till lenders complete their execution; this optimism is advantageous only when lenders successfully complete their executions. While the policy of using uncommitted data items may result in the chain of dependencies responsible for the cascading aborts, the OPT protocol restricts the length of chain to only one by not allowing the borrowers to simultaneously become lenders. Therefore, it doesn't suffer from a cascading abort problem. It provides a considerable performance improvement over 2PC.

Moreover, two variants of the OPT is also suggested: Healthy-OPT and Shadow-OPT (Gupta, Haritsa, & Ramamritham, 1997). In the Healthy-OPT, every executing transaction is assigned a health factor (HF), and a transaction can become lender only when its HF value is greater than or equal to some threshold value. Obviously, the performance of the system heavily varies with change in the chosen threshold value. In the Shadow-OPT, the cohort originates a shadow (replica of itself) at the instance it borrows some uncommitted data item. Moreover, the original version of the borrower cohort continues its execution as usual even after borrowing uncommitted data item while the shadow cohort is blocked right after being forked off as a separate cohort. In case lenders successfully commit, the shadow cohort is discarded since optimistic borrowing done its job well. Otherwise, if any of the lenders (who have a dependency with this cohort) aborts, the shadow cohort is activated, and the original cohort is aborted. Thus, the Shadow-OPT saves the borrower cohort from restarting its execution in case of an unsuccessful lending-borrowing event and provides a feature so that the borrower cohort can resume its processing from the point the borrowing is made. The detailed simulation results showed that the Healthy-OPT performs reasonably fairer than the Shadow-OPT.

Later, the ‘Permits Reading of Modified Prepared Data for Timeliness’ (PROMPT) protocol is proposed; it is an extension/ integration of the work done in the OPT protocol and its variants (Haritsa, Ramamritham, & Gupta, 2000). The PROMPT provides features like controlled optimistic access to uncommitted data, active abort, silent kill, and healthy lending. Though the PROMPT protocol remained the standard for a long time to assess the implementation-performance of other real-time commit protocols that came after it, several shortcomings of this protocol are raised by researchers with time. Some key developments are discussed below.

To reduce data inaccessibility and priority inversion duration, the Double Space Commit (2SC) protocol exhibits two properties (Qin & Liu, 2003). The 2SC protocol, unlike PROMPT, has two main features: (i). permits a non-healthy prepared transaction to lend the data, that is earlier locked by it in shared mode, to the transactions that lead to commit dependency with it. (ii). in case of the abort of the prepared lender transaction, transactions from its abort dependency set are aborted. Such abort does not affect the execution of transactions that are in the commit dependency set of the prepared lender transaction. The 2SC protocol performs fairer than the PROMPT protocol. The ‘Static two-phase locking and high priority based, Write-update type, Ideal for Fast and Timeliness commit protocol’ (SWIFT) protocol (Shanker, Misra, & Sarje, 2006) analyzed all type of dependencies that may happen during execute-commit conflicts. The SWIFT divides the execution phase of the cohort into two phases: (i). locking and (ii). processing phase. Here, the cohort sends an early message named as WORKSTARTED message just after the completion of the locking phase. This leads to a situation in which the WORKDONE message need not be sent after the completion of the processing phase of executing cohort. The changed scenario leads to an improved system performance since the delay involved in sending the WORKDONE message is eliminated; it became possible through an innovative means of overlapping the send event of WORKSTARTED message and the processing time involved in executing a cohort. The SWIFT protocol enhanced the system performance as compared to PROMPT and 2SC protocol by reducing transaction miss percentage up to 10% (Shanker, Misra, & Sarje, 2009). The working of the SWIFT protocol may be clearly understood using Figure 1.

Figure 1. Level of Data Accessibility in SWIFT Protocol

The Extended SWIFT protocol (Aakash, Gaurav, Gupta, & Kumar, 2015), proposed by Ankit Aakash et al., discussed the database inconsistency problem resulting due to Read-Read access in the DRTDBS. It also uses the Lender-Borrower approach to deal with the priority inversion. ACTIVE protocol (Shanker, Agarwal, Tiwari, Goel, & Srivastava, 2010) categorizes borrowers as following; (i). Commit dependent

borrower and (ii). Abort dependent borrower. To reduce the data inaccessibility, the commit dependent borrowers are further allowed to lend their uncommitted data. Here, a metric named ‘borrowing factor’ is formulated and computed for each borrower distinctly. This ensures that the lock can be granted to a second-step abort dependent borrower fruitfully by a first-step commit dependent borrower. The working of the ACTIVE protocol may be clearly understood using Figure 2.

Figure 2. Level of Data Accessibility in ACTIVE Protocol

In PERDURABLE protocol (Shanker, Vidyareddi, & Shukla, 2012), a lender writer cohort that has already provided access to uncommitted data to an abort dependent borrower cohort can provide access to the same data in shared mode to other borrowers. It further improves the data item availability by allowing all the locks, that were not required during the processing phase, to be released before the start of the commit phase. The working of the PERDURABLE protocol may be clearly understood using Figure 3.

Figure 3. Level of Data Accessibility in PERDURABLE Protocol

As a part of one more advancement in this direction, an Improved Data Lending based Distributed Real-Time Commit (IDRC) protocol (Pandey & Shanker, 2017a) has been developed; it lessens the effect of the Executing-Committing conflict on the DRTDBS performance by providing the better data accessibility in comparison with earlier protocols. It does so by allowing the commit-dependent first-step borrower (who has already provided access of uncommitted data item to the second-step abort dependent borrower) to lend the same data item in shared mode to numerous other second-step borrower cohorts.

Most of the above-discussed protocols, extending the PROMPT protocol, specifically reduce data inaccessibility to achieve their common goal. As a successor of them, the proposed Early Data-Lending based Real-Time Commit (EDRC) protocol provides a feature to start the lending process just after the completion of the data processing task during the processing phase obviously after locking phase. As a result of allowing lending to happen even before the voting phase of a cohort, the EDRC reduces the transaction deadline miss percentage.

EDRC: A PROPOSED REAL-TIME COMMIT PROTOCOL

Several real-time conflict resolution strategies (concurrency control protocols and commit protocols) have been proposed till date for resolution of data conflicts among concurrently executing DRTTs. These strategies heavily affect DRTDBS performance. Lower the wastage of resources as a consequence of aborts, higher will be the chance of completion of the concurrently executing DRTTs. But there is a need to ensure that the protocols should be well-concentrated toward valuing the priority order instead of reducing wastage of resources or increasing throughput. Hence, the primary DRTDBS performance objective is to reduce the number of DRTTs missing their deadlines; obviously the consistent and atomic commitment of DRTTs must be guaranteed as well. The above objective can be achieved by means of increasing data accessibility. However, blocking the DRTTs — the main source of data inaccessibility — is necessary to ensure the database consistency. The data inaccessibility problem may occur when a set of requesting DRTTs gets blocked from accessing an uncommitted data item which is currently being held by a prepared cohort of other DRTT. So, data conflicts among concurrently executing DRTTs may give birth to the data inaccessibility.

To address the above problems more efficiently, an Early Data-Lending based Real-Time Commit (EDRC) protocol is proposed which not only categorizes the data conflicts among DRTTs but also provides different ways to handle these newly described data conflicts. The EDRC protocol optimistically reduces wastage of resources by employing the cooperative lender-borrower strategy through the early start of data lending during the concurrent execution of DRTTs, and in turn reduces the number of DRTTs missing their deadlines. Another advantage with EDRC protocol is that the positive features of the existing lender-borrower based real-time commit protocols can be easily integrated with it. The proposed protocol is an extension of the SWIFT protocol (Shanker, Misra, & Sarje, 2006). It divides the execution phase into 2 phases: the locking phase and processing phase.

The cohorts lock the data items required by them during their locking phase only. After completion of the locking phase, cohorts send WORKSTARTED messages to their respective coordinators; this event occurs at the beginning of the processing phase. After receiving the WORKSTARTED message from its cohorts, the coordinator sends PREPARE message to all its cohorts at time t . This time is computed as follows.

$$t = \text{MAX} \{t_i + \text{ProcessingTime}_i\} - t_{CD}$$

where t_i = arrival time of cohort_{*i*}'s WORKSTARTED message, $ProcessingTime_i$ = Processing time involved in executing cohort_{*i*}, and t_{CD} = Comm. Delay.

To improve the data accessibility, the EDRC protocol re-categorizes the data conflict occurring among DRTTs as following: locking-locking conflicts, locking-processing conflicts, and locking-committing conflicts. The locking-locking conflict and locking-processing conflict both may occur between executing transactions; hence, they are a result of the further classification of execute-execute conflict (Pandey & Shanker, Transaction Scheduling Protocols For Controlling Priority Inversion: A Review, 2020), a widely studied data conflict in literature. The proposed protocol, in contrary to the SWIFT, handles the locking- locking and locking-processing conflicts differently. The locking-locking conflict is handled in the same way as execute-execute conflict handled by previously developed protocols simply by aborting the DRTT with low priority in case of priority inversion.

The handling of the locking-processing conflict, however, makes the EDRC protocol better than SWIFT. In case of the locking-processing conflict, there is a chance that the executing cohort of a low priority DRTT may complete its execution without impairing some other executing cohort(s) of high priority DRTT(s) that have conflicting data access requirements. This prospect is exploited by initiating the lending process at an early stage, given that this executing cohort which belongs to the low priority DRTT has not only sent the WORKSTARTED message to its coordinator but also completed its data processing task before the occurrence of the above locking-processing data conflict.

Let us consider the case where some cohort of high priority DRTT requests access to the data item in its locking phase which is already being locked by executing cohort of some other low priority DRTT. This conflict may be named as locking-processing conflict. For resolving execute-execute conflicts, previous real-time commit protocols had a provision to simply abort the lock holding DRTT in case its priority is lower than that of lock requesting DRTT. In contrary to this, the EDRC protocol provides a mechanism to start the lending process among DRTTs just after the completion of the data processing task by a cohort in case of data conflict with this cohort. To efficiently handle the data conflict among executing transactions, the lender-borrower approach is utilized as below.

1. When the request for accessing the data item which is already modified by an executing cohort of some DRTT is generated by another executing cohort of some other DRTT, it is checked whether the lock holding cohort has completed its data processing task or not.
2. If the lock holding cohort has completed its data processing task before such conflicting lock request then it can immediately provide dirty data item to the borrower DRTT in a dependent manner as opposed to existing real-time commit protocols; otherwise, if lock holding cohort's data processing task is not completed, then such conflict is resolved using the S2PL-HP protocol.
3. By doing this, the priority inversion is not only optimistically handled but the resource wastage is also avoided to some extent. It results in a reduction in overall DRTT execution time, an increase in data accessibility and the most important minimization in the transaction deadline miss percentage.

Classification of Transactional Dependency

Transactional dependency may arise among a set of DRTTs requiring access to a conflicting data item without being blocked. Such dependencies restrict the commit order of conflicting DRTTs. There can be two types of transactional dependencies: (i). transactional commit dependency (TCD) and (ii). transactional abort dependency (TAD). When the DRTT, ' T_i ' requests a write lock on a data read by other DRTT ' T ', it leads to a TCD from T_i to T represented by T_i TCD T . Here, the younger T_i is not enabled

to commit until the older T has committed. When the DRTT, ' T_i ' performs a read/write operation on an uncommitted data modified/ updated by DRTT 'T', a TAD is established from T_i to T represented by T_i TAD T. Here, the younger T_i must commit after the older T and the abort of T forces T_i to abort. Each site with executing DRTTs maintains a table with the following information about local active cohorts. For the ACID compliant DRTT execution, the above two transactional dependencies need to be controlled logically.

Computation of Health Factor

Health Factor (HF) parameter is used to predict whether the requested lending is going to be fruitful or not. The HF is computed for each lender to make the lending decision intelligently — only when doing so benefits the transactions that are going to cooperate through the idea of lending-borrowing activity. Mathematically, the HF can be defined as (Haritsa, Ramamritham, & Gupta, 2000).

$$HealthFactor(HF) = \frac{T_{left}}{Min_{time}}$$

Here, T_{left} is the time left until the executing DRTT's deadline, and Min_{time} is the minimum time necessary for commit processing.

In previous protocols, the HF is computed at the time when the coordinator of a DRTT is about to send the PREPARE message to its participating cohorts. In the proposed EDRC protocol, however, the health factor is computed at an earlier time when the cohort is ready to send a WORKSTARTED message to its coordinator. Thereby, it opens the way to start the lending process earlier. The MinHF is a threshold HF value used to decide whether the data held by committing/processing DRTT can be lent to executing (locking) cohort or not. The variable MinHF is the key factor influencing the performance of the EDRC protocol. Therefore, it is always required to have an appropriate value of MinHF for better performance. For $MinHF = 0$, the T_{left} is required to be 0. This means, executing DRTT is ultimately going to miss its deadline, and therefore lending will be of no use. For $MinHF = \infty$, the borrowing feature is disabled; thus, the EDRC protocol will behave like the classic 2PC. When $MinHF = 1$, the fruitful lending is possible. In our experiments, the MinHF is assumed to be 1.2 (Shanker, Misra, & Sarje, 2006) since it is the right value for efficiently controlling the optimistic data access. It is the same as

Figure 4. Level of Data Accessibility in EDRC Protocol

the value considered by all the previous protocols (Qin & Liu, 2003) (Qin, Liu, & Yang, 2003) (QIN & LIU, 2002). The success percentage of the lending-borrowing event is found to be much better than for $\text{MinHF} = 1.2$ as compared to that of $\text{MinHF} = 1$.

Figure 4 represents the level of data accessibility with the EDRC protocol. As it is clearly interpreted from the above figure, the dependency among the set of transactions may occur even when they all are in the execution phase; of course, they are in different sub-phases of execution phases. Such action leads to increased data accessibility which is crucial in today's real-world transactional data processing.

PERFORMANCE EVALUATION

For the experimental assessment of the EDRC protocol, there is no readymade simulation tool available (Ulusoy, 1995) (Taina & Son, 1999). The event-driven simulation is often used in most of the average and substantially large size database applications consisting of transactions executing concurrently and competing for the shared resource(s). Therefore, a discrete event-driven simulation is developed using C language to access the performance of the proposed protocol. The performance of the EDRC protocol is measured using the metric named "Miss Percentage". It is the percentage of transactions that are aborted/killed as a result of their deadline miss. Being an extension of the SWIFT protocol, the model assumptions, simulations parameter and other parameter detail can be obtained by referring (Shanker, Misra, & Sarje, 2006) since analogues environment is created for experimentation and comparison purposes. For this reason, the EDRC protocol's performance is compared with PROMPT, 2SC and SWIFT Protocol. To investigate the performance of the EDRC, when applied to a DRTDBS, a wide range of global as well as local transactions are generated.

Figures 5-7 present the transaction miss percentage in the disk resident databases under resource and data contention at communication delay of either 10 milliseconds or 1 millisecond with different transaction arrival rates.

Figure 5. Transaction Arrival Rate vs Transaction Miss Percentage: 1 millisecond comm. delay and normal load

Figure 6. Transaction Arrival Rate vs Transaction Miss Percentage: 1 millisecond comm. delay and heavy load

Figure 7. Transaction Arrival Rate vs Transaction Miss Percentage: 10 millisecond comm. delay and normal & heavy load

It is seen that the proposed EDRC protocol performs better than PROMPT, 2SC and SWIFT protocol. The main reasons for the improvement in performance are refined classification and handling of data conflicts among concurrently executing transactions, and thus increased data accessibility in the EDRC protocol.

FUTURE RESEARCH TRENDS

The point-to-point insight about future research opportunities from the DRTDBS perspective is provided below (Pandey & Shanker, 2020).

1. The data conflicts (locking-locking, locking-processing & locking-committing conflict) and possible priority inversion because of them are one of the main reasons for degraded system performance. Therefore, existing transaction scheduling algorithms need a fresh look from the perspective of efficiently resolving data conflicts. The priority inheritance approach has a potential to become a promising approach in dealing with priority inversion while scheduling DRTTs as it can be utilized to improve existing concurrency control protocols and commit protocols (Pandey & Shanker, 2017b) (Pandey & Shanker, 2018a) (Pandey & Shanker, 2018b) (Pandey & Shanker, 2018c).
2. Only a few research works have been done in the context of the handling of non-database operations; though, research in this direction may be useful to improve underlying system performance. The Non-Database Operations Aware Priority Ceiling Protocol (N-DOAP) is a recent effort in this direction (Singh, Pandey, & Shanker, 2019). In the N-DOAP protocol, the database operations are given preference over non-database operations. Consideration of the aspect of non-database operations resulted in the improvement of performance.
3. In RTDBS with one or more processor, there is a need of an effective and workable approach to reduce both transaction miss percentage and power consumption (Bambagini, Marinoni, Aydin, & Buttazzo, 2016) (Baruah, Bertogna, & Buttazzo, 2015) (Guo, Bhuiyan, Saifullah, Guan, & Xiong, 2017). One way to do so is by merging the similar real-time queries for the decrement of repeated data processing and accessing while doing power management dynamically (Kang K., Reducing deadline misses and power consumption in real-time databases, 2016) (Kang & Chung, 2017). It is still not clear how a one deadline can be assigned to a query in real time environment that in fact combines many real-time queries with the outset of different deadlines into one (Madden, Franklin, Hellerstein, & Hong, 2005) avoiding priority inversion (Kang K., 2018). Related work in this area is relatively scarce in spite of being a very important one.
4. It will be interesting to widen the discussion of priority inversion problem of mobile DRTDBS (Lam, Kuo, Tsang, & Law, 2000) (Lei, Zhao, Chen, & Yuan, 2009) (Swaroop, Gupta, & Shanker, 2011), replicated DRTDBS (Xiong, Ramamritham, Haritsa, & Stankovic, 2002) (Wei, Aslinger, Son, & Stankovic, 2004, August) (Srivastava, Shankar, & Tiwari, 2012), nested (Abdouli, Sadeg, Amanton, & Alimi, 2005, September) (Moon & Lee, 2011), active DRTDBS (Lam, Law, & Lee, 2000), and mobile ad-hoc network (MANET) databases (Xing & Gruenwald, 2011, August) (Xing & Gruenwald, 2013). More promising research efforts are required to develop advanced value based real-time commercial products.
5. Considering the wide-spreading impact of database system based applications in recent days, researchers also started working to improve the performance of conventional databases systems by improving classic 2PC and 2PL (Gupta & Sadoghi, March, 2018) (Gupta & Sadoghi, 2019) (Pandey, Pandey, & Shanker, 2019) (Harding, Aken, Pavlo, & Stonebraker, 2016).

CONCLUSION

The proposed EDRC protocol optimistically utilized the Lender-Borrower approach. It recategorized the data conflict as a locking-locking conflict, locking-processing conflict, and locking-committing conflict. The novel feature of this protocol is that it facilitates to start the lending process just after the completion of the data processing task of the cohort. For guaranteeing the feature of early lending, the health factor of a cohort is computed at a time when it sends WORKSTARTED message to its coordinator. This overlaps the execution and commit phase, and thereby reduces the overall completion time of global transaction. As a result, it reduced the transaction deadline miss percentage.

Future research in the direction of advancement of existing state-of-the-art lender-borrower approach based transaction scheduling protocols is required to come up with advanced user oriented commercial products/services.

KEY TERMS AND DEFINITIONS

Distributed Real-Time Database System (DRTDBS): The DRTDBS consists of multiple data sites that are connected through an underlying computer network specifically used to run applications based on distributed real-time transactions.

Firm Distributed Real-Time Transaction (Firm DRTT): The firm DRTT is killed in case it misses its deadline because its outcome has no value after the deadline miss.

Hard Distributed Real-Time Transaction (Hard DRTT): The hard DRTT must be finished before its deadline; otherwise, it may lead to a potentially catastrophic consequence.

Locking-Committing Conflict: The locking-committing conflict is handled in the same way as execute-commit conflict.

Locking-Locking Conflict: The locking-locking conflict is handled simply by aborting the DRTT with low priority in case of priority inversion.

Locking-Processing Conflict: The locking-processing conflict is handled based on the status of the cohort i.e. whether it has sent WORKSTARTED message or not, and lending may be allowed only when the cohort has already sent WORKSTARTED message.

Real-Time Commit Protocols: Ensure that either all the effects of the DRTT persist or none of them irrespective of any such failure.

Soft Distributed Real-Time Transaction (Soft DRTT): The soft DRTT is not killed/aborted in case of its deadline miss because the result has some value (obviously degrading) even after the deadline miss.

Application of Data Mining in Smart Grid Technology

INTRODUCTION

Smart grid technology is a radical and creative approach for improvisation in existing passive power grid. Assimilation of power and communication infrastructures is inevitable for the design and deployment of an imminent smart grid technology. The grid is called ‘Smart’ as it is accomplished with intelligent devices for decision making. Some of the substantial features of smart grid technology are bidirectional communication, renewable integration, active consumer participation, distribution automation, advanced metering infrastructure, supervisory control and data acquisition and complete management of entire power grid through wireless communication protocols and technologies. Smart grid communication infrastructure is a gigantic architecture with massive amount of data communication between various hierarchical network layers (Farooq & Jung, 2014). Full duplex data communication is required for monitoring, control, security, management and fault diagnosis of entire power grid (Mahmood et al., 2015). Management of complex, hierarchical and heterogeneous smart grid communication infrastructure necessitates data collection, storage, processing, analysis, retrieval and communication for self-healing and complete automation. Collection, interpretation and analysis of massive quantity of data generated in smart grid operation are critical, inevitable and complex tasks (Gungor et al., 2010). Data mining techniques can be an effective solution for smart grid operation and management. Data mining is essential for converting information into knowledge (Wijaya, T., 2013). Knowledge discovery and data mining are interdisciplinary tasks in the context of smart grid network. Database management and data mining are the two significant aspects of a database system. Database management deals with processing and storage of data and data mining deals with discovery and abstraction of knowledge for the purpose of decision making. Data mining is a computational process for data scrutiny and analysis. Data analysis is unavoidable for unambiguous knowledge discovery as well as decision making practices. Data mining is necessary for analysis of various statistics associated with power generation, distribution automation, data communications, billing, consumer participation, and fault diagnosis in smart power grid. In Smart grid, accumulation of real time data is inevitable. Data mining techniques are required when data is continuously collected on real time basis (Atzmueller et al., 2013). The pattern of gigantic sets of data

DOI: 10.4018/978-1-7998-3479-3.ch056

can be effectively extracted and scrutinized with the use of different data mining techniques for energy efficiency, reliability and real time decision making. This chapter is expected to serve as a comprehensive analysis and review of application of data mining techniques in generation, transmission, distribution and utilization of energy in smart grid infrastructure.

BACKGROUND

An electrical power grid carries the electricity from generation unit to the consumption unit. An existing power grid is being transformed through the design, development and deployment of smart grid technology. An existing grid is passive in terms of real time monitoring, control, consumer participation, fault diagnosis, disaster recovery, and real time communication of energy related statistics. There are enormous challenges such as theft and distribution losses, scarcity of primary energy sources, aging and underperformance of coal based power plants etc. An existing grid is incapable of addressing these issue in effective manner due to lack of data communication between various components of energy generation, transmission, distribution and utilization. Smart grid can be defined in diverse ways as per its functional, technological or constructive aspects. (United States Department of Energy, 2009) defines the Smart Grid as: 'A smart grid uses digital technology to improve reliability, security, and efficiency (both economic and energy) of the electric system from large generation, through the delivery systems to electricity consumers and a growing number of distributed-generation and storage resources.' Smart Grid includes various communications protocols and hierarchical network layers. (Farooq & Jung, 2014) have discussed various choices available for realization of smart grid communication networks. The hierarchical design of Smart power grid comprises of home, neighborhood and wide area networks. These hierarchical networks exchange information for monitoring and control of smart grid operations. Mahmood et al. have discussed and reviewed various wireless communication protocols for smart grid applications. Massive quantity of data communication is required for the realization of smart grid technology. An unambiguous knowledge discovery along with data analysis is vital for reliable and proficient management of smart grid. The prime concern is an extraction, analysis, interpretation and management of exploded data from various measurement devices and sensors in smart grid. Smart grid is a multifaceted technology. Moreover, the nature of data in smart grid technology is dynamic and distributed (Saputro et al., 2012). The traditional data mining processes are focused, centralized, static, bounded and non-real time. It does not have energy or speed constraints. Smart grid technology incorporates wireless sensor networks and Internet of Things which are two diverse areas in terms of data mining and knowledge detection processes. The traditional data mining techniques cannot be directly applied to wireless sensor networks due to their restricted computational, power and storage capabilities. Internet of things is meant for dynamic, swift and near real time data which necessitates novel data mining approach. This chapter illustrates conceptual description of smart grid technology and application of data mining techniques in generation, transmission, distribution and utilization of electrical energy.

CONCEPT OF SMART GRID TECHNOLOGY

An existing electrical grid is being transformed through deployment of smart grid technology. The main difference between an existing power grid and smart grid is in terms of full duplex communication and real time management of energy statistics. Smart grid is an assimilation of power as well as information

and communication infrastructures (Erol-Kantarci et al., 2011). The key features of smart grid technology includes real time monitoring, management and control of energy parameters, high penetration of renewable energy resources, advanced metering infrastructure, supervisory control and data acquisition, fault diagnosis, disaster recovery, self-healing, active consumer participation, demand side management, distribution automation and reduction of greenhouse gas emissions (Chen et al., 2006). Smart grid comprises of various hierarchical communication network layers such as home area network, neighborhood area network and wide area network. Home area network is meant for consumer premises. The range of this network is few hundred meters and it facilitates the communication between utility and consumers (Sun et al., 2009). Home area network consists of communication transmitters, receivers, intelligent electronic devices, consumer electronic devices, energy meters and renewable energy sources. Neighborhood area network consist of several home area networks. The data collected by smart meters in home area network is forwarded to wide area network through neighborhood area network. The area of neighborhood area network is few kilometers. Wireless local area network, cellular communication standards and power line communication technologies can be used for implementation of neighborhood area network (Patel et al., 2011). Wide area network connects several neighborhood area networks. Wide area requires very high bandwidth for its operation and management. Wide area network is appropriate for supervisory control and data acquisition systems for monitoring, data acquisition, control, and management of power grid. Internet of things technology is inevitable at each stage of hierarchical network for connectivity and integration of various equipment and meters. Various cellular communication standards and power line communication technologies are suitable choices for realization of wide area network (Chhaya et al.,

Figure 1. Smart grid communication infrastructure

2017). Hierarchical architecture ensures reliable communication of information at generation, transmission, distribution and control of smart grid but still there are enormous challenges to be overcome for realization of full-fledged smart grid communication infrastructure. Realization of hierarchical network necessitates massive data communication and analysis for its operational security and reliability (Xu et al., 2014). Data mining tasks and techniques are inevitable for functional efficiency of Smart Grid networks. Figure 1 shows the architecture of smart grid communication network.

PROCESS OF DATA MINING

Data mining is expedient for optimization of Smart Grid network. As functional and operational efficiency of smart grid is based on decision making, different data mining techniques are suitable for generation, transmission, distribution and consumption stages of smart power system. The mining of information from large volume of data is done through the methods from database systems, artificial intelligence, machine learning and statistics. Realization of Smart grid is reliant on integration of information and communication technology with power grid as fundamental concepts and operations of mechanical and electrical apparatus will remain unchanged. The innovative approach is to integrate these devices with smart sensors and actuators for extraction and communication of information. This information is useful for monitoring and control purpose. The patterns of gigantic sets of data can be effectively extracted and analyzed with the use of data mining techniques which results into energy efficiency, reliability and real time decision making. The use of data mining technology is to discover reliable, valid and understandable information. Figure 2 shows the process of data mining.

Data mining can be defined as a computational process to extract and scrutinise the information from massive amount of data sets by using techniques such as artificial intelligence, machine learning, database systems, and statistics (Jiawei et al., 2000). It is a collaborative and iterative process of knowledge discovery. Discovery of patterns from huge sets of data generally includes following tasks.

- **Clustering:** The process of clustering identifies similar objects in the data and clusters the same. It is a grouping of identical objects in huge sets of data.
- **Anomaly Detection:** This process identifies deviation or unusual data.
- **Classification:** It is a process of generalization of known structure for application of novel data.
- **Summarization:** It deals with report generation and visualization by compact depiction of data sets.
- **Regression:** It finds the function for modelling of data with minimum errors.
- **Association rule learning:** This process finds reliance or connection between different variables.
- **Frequent Pattern mining:** It is a process to find the motifs or patterns which occur frequently during pattern extracting process.

Data mining process can be rarely performed with the data sets in their original forms. So, data cleaning, aggregation, normalization, identification of noisy values and compression can be performed before data mining process. Various data mining methods are used in combination or independently to perform various data mining tasks.

Figure 2. Process of data mining

APPLICATION OF DATA MINING IN SMART GRID

Data mining tasks and methods are required to identify suitable input as well as output variables and to extract the features of these variables. Data mining methods can be used to identify power system conditions such as emergency, normal, restorative or alert (Mahmood et al., 2013).

Applications of Data Mining in Generation

As the nature of various generation sources is quite diverse, data mining has extensive applications in generation. Association rule mining can be used for fault identification and troubleshooting of coal based power plant. Statistical analysis can be used to analyse the performance and operational characteristics of renewable energy sources due to their unpredictable features (Cai, T., 2016). Photovoltaic generation

system behaviour and failure analysis can be performed using data mining techniques (Serrano-Luján et al, 2015). Various regression tasks can be performed for load profile forecasting. In fossil fuel based power plant, supply and demand can be synchronised by load forecasting which may result into saving of revenue. This method can also be applied to renewable energy resources. Load forecasting can be performed for very short term (for hours), medium term (for few weeks), or long term (for years). Load forecasting can be performed using multiple regression, artificial neural network, or time series.

Applications of Data Mining in Transmission and Distribution

Wireless sensor is a vital component of smart grid network. Wireless sensor networks are used for collection and communication of data among smart grid communication networks. Wireless sensor network comprises of sensor, storage unit, communication transceivers, power supply unit, location finding system and actuator. Wireless sensor networks are meant for real time monitoring and control of energy statistics in smart grid network (Chhaya et al., 2017).

Estimation of power system is performed for evaluation of metered as well as unmetered connections and quantities of whole power system. It is useful for power failure prevention and grid stability. Association rule mining and fuzzy logic can be used for power system estimation. Transformer insulation oil is stable at high temperature and retains excellent insulation properties. Dissolved Gas Analysis is used to estimate the amount of dissolved gases in transformer insulating oil. It is useful for fault diagnosis and maintenance of transformer. Artificial intelligence can be applied to perform dissolved gas analysis. Integration of renewable energy resources is the most prominent feature of Smart Grid in the context of reduction of GHG emissions and energy efficiency. Micro grid facilitates the high penetration of renewable energy resources. It can operate in two modes namely grid connected and island mode. In island mode, renewable energy resources self-reliantly provide power to consumers. Islanding can also be used when the grid power is not available or there is a fault in the network. Island detection is also important for grid stability when many distributed energy sources are connected to power grid. Island detection can be performed using fuzzy membership function using rule based approach. Fault identification can be performed using artificial neural networks and regression processes. Data mining techniques are useful for secured metering system (Faisal et al., 2012).

Power quality is a crucial aspect of Smart Grid system. Power quality can be evaluated in terms of various electrical parameters such as surges, spikes, harmonics, droops, sags, and instabilities (Hongke & Linhai, 2010). Online analytical processing can be performed for power quality evaluation. Contingency analysis is performed for identification of potential failures in the power system and their effect on the system. This analysis can also be used to evaluate the tolerance of power system against various fault conditions. Electricity price forecasting is an important parameter for market operation. It is imperative for energy distributors as well as consumers. Regression techniques and artificial neural networks can be used for forecasting of energy prices. Active consumer participation is a key characteristic of Smart grid network. Consumer can monitor and manage their energy utilization through real time communication of information. Dynamic billing cycle can be used through load forecasting. Short duration load forecasting is possible using data mining techniques. This forecasting majorly impacts future energy consumption pattern and dynamic pricing. Neural network can be used for electricity load and price forecasting (Zahid et al., 2019).

Applications of Data Mining in Utilization

Consumer is of prime importance in Smart Grid network. Smart Grid technology facilitates an active participation of consumers. Consumers can monitor and control their energy usage as they will be continuously updated with various metering related information. They can optimize their charge of energy usage by getting information regarding time of the day billing information. Advanced metering infrastructure is also an inevitable part of Smart Grid. It can be defined as a full duplex network between utilities and customer premises. Security of advanced metering infrastructure network is the most critical aspect of smart grid network. National Institute of Standards and Technology has proposed guidelines for smart grid cyber security issues. (Faisal et al., 2012) have proposed stream data mining techniques and algorithms for intrusion detection system for advanced metering infrastructure network. Classification methods of data mining can also be used for advanced metering infrastructure network security and attack and intrusion resilience. Load profiling and forecasting are very important parameters for energy efficiency and reliability. Smart micro grid enhances the penetration of renewable energy resources in power system. Data mining techniques are apt solution for analysis of uncertain behaviour of renewable energy resources (Cai, T., 2016). In case of Micro grids, where user or a community can select various parameters of Grid, renewable operations and time of usage, load forecasting is a crucial requirement. It is also important for Building Management System. The comparative study of seven data mining techniques for load forecasting in Building Management System is explored in. Support vector machine, autoregressive method, neural networks polynomial model etc. can be used for building load forecasting. Electricity price forecasting for consumer applications can be performed using regression techniques. Different hybrid data mining methods can also be developed for various applications in Smart Grid.

Decision tree is used to explore the hidden relation relationship between input and output. It is used to predict and assess the operating conditions of power system. It can also be used for control, protection, fault diagnosis and load forecasting of power distribution system (Liu et al., 2013).

Data Mining Techniques for Wireless Sensor Networks

Wireless sensor network is a vital part of smart grid communication network as it communicates real time energy statistics to different smart grid hierarchical network layers. Wireless sensor network comprises of communication transceivers, storage unit, power supply unit, processing unit, sensors, and actuator. Wireless sensor network is an inevitable part of different smart grid network layers. Furthermore wireless sensor network is a vulnerable entity due to its limited storage, processing and computational capabilities. The traditional data mining techniques are used for static, non-real time, centralized and bounded networks with high memory, computing and power capabilities. Moreover, these networks do not require very high speed communications. Wireless sensor networks have limited capabilities and require the processing of real time and high speed dynamic data (Mahmood et al., 2013). Figure 3 illustrates the classification of various data mining techniques for wireless sensor network.

Wireless sensor comprises of enormous number of nodes for diverse set of communication standards and networks for smart grid heterogeneous and hierarchical networks. The flow of data is swift, continuous and dynamic. Wireless sensor network is an integral component of Internet of Things which forms a complex and heterogeneous smart grid network.

The purpose of data mining techniques is to extract useful and understandable information from the fast and continuous flow of data. In the centralized approach of data mining, the data is collected at a single central site and then the algorithms are applied for extraction of information from the accumulated

Figure 3. Classification of data mining techniques for wireless sensor network

data. It is like a warehousing and mining of data. This approach is inappropriate as well as challenging due to reasons like gigantic amount of data, bandwidth limitations, storage issues and computational restrictions. The distributed processing of data overcomes the challenges imposed by centralized data mining. Distributed data mining reduces the issues related to storage, power and bandwidth. Smart grid applications are time-critical as real time data is to be communicated to central controller. Distributed data mining techniques prevents gigantic set of raw data to be sent to sink node which is beneficial for constrained wireless sensor networks (Mahmood et al., 2013). Furthermore, there is a trade-off between the performance of wireless sensor network in terms of restricted capabilities and its performance based on specific application. Wireless sensor network performance requires better storage, computational and energy capabilities while application oriented approach requires accuracy, reliability, robustness scal-

ability and fault tolerance of the network. Thus the classification of data mining techniques is carried out on the basis of performance versus application based approach.

CHALLENGES IN DATA MINING OF SMART GRID BIG DATA

Smart grid is a complex hierarchical network with heterogeneous networks and standards. Huge amount of information exchange between diverse intelligent electronic devices and networks is essential for operation and management of smart grid network. Extraction of useful information and analysis of data is a challenging task.

- Handling the gigantic volume of data is the biggest challenge to overcome as knowledge extraction from terabytes, petabytes or zettabytes of data requires proficient algorithms and data mining techniques.
- It is a challenging task to handle heterogeneous data types retrieved from heterogeneous networks, devices, and sources. With an inevitable inclusion of Internet of things in smart grid technology, Internet will be flooded with information communicated between diverse IP based devices and networks.
- The format as well as volume of data is very complex and thus it is challenging to extract an information from gigantic set of heterogeneous and complex data.
- Smart grid comprises of diverse set of networks with heterogeneous standards and technologies. The biggest complexity lies in handling the data from wireless sensor network which is a constrained network in terms of memory, computational proficiency, and power. It is difficult to maintain reliability and accuracy of data from this type of networks.
- The data communication in smart grid hierarchical; networks is very fast as it is near real time data communication. The processing and knowledge discovery from this kind of enormous, rapid and real time data is difficult and complicated task.
- Internet of things is an inevitable component of smart grid network which requires online data mining. Existing data mining and knowledge discovery techniques are offline in nature. The challenge is to handle and process distributed and online data stream.
- Wireless sensor nodes are spreaded over remote and harsh locations. It is challenging to deal with security, heterogeneity, noise, uncertainty, and dynamics of data. Fault finding and correction of incomplete and insufficient data is also challenging.

SOLUTIONS AND RECOMMENDATIONS

The traditional data mining techniques are not suitable for smart grid applications as they are meant for static, non-real time, multipass, bounded and low speed data with no constraints related to network, bandwidth, speed, computations and power. The novel techniques should be developed for offline knowledge discovery and online as well as distributed data processing for Internet of things and wireless sensor network based smart grid network. Data mining and knowledge discovery techniques must consider resource constraints and network topology of wireless sensor nodes. The techniques should be developed for uncomplicated computational algorithms and techniques. Heterogeneous data communication between networks and attribute, spatial and temporal correlations between various sensor nodes

should be consider while developing new data mining and information extraction techniques. Hybrid data mining techniques with single pass algorithms and local models should be developed.

FUTURE RESEARCH DIRECTIONS

Smart grid communication infrastructure is a hierarchical and complex network comprising of heterogeneous communication devices and networks. Data mining and knowledge discovery is the process of information extraction from the gigantic set of raw data. This chapter is expected to serve as a directive for future research endeavors in the field of big data mining techniques. The future research is required for development of data mining algorithms and techniques for wireless sensor networks, Internet of things and heterogeneous networks. Distributed and dynamic approach is required for mining of diverse set of gigantic and real time data. Network dynamics and resource constraints must be consider while developing novel data mining techniques and algorithms. A hybrid approach for secured and fault tolerant information extraction can be considered for future research endeavors.

CONCLUSION

Smart Grid is the most revolutionary technology of present era. An integration of Information and communication technology is inevitable to augment intelligence to smart grid. Extraction of accurate information is possible with the use of data mining methods and tasks. The paper illustrates fundamental components of smart grid communication infrastructure. In this paper, application of data mining in power system generation, transmission, distribution, and consumption are discussed. Furthermore, Internet of things and wireless sensor networks are the vital components of future smart grid technology. The traditional data mining techniques developed for static, non-real time, centralized and bounded networks are not suitable for heterogeneous smart grid communication network. There is a need of rigorous research and development for exploration of data mining techniques for smart grid applications. Smart grid security aspects and fault detection and trouble are the key areas for exploration and future research endeavours. This article is expected to serve as a comprehensive review of potential data mining applications in smart grid research and deployment.

KEY TERMS AND DEFINITIONS

Data Mining: A process of extracting information from raw data sets.

Smart Grid: An electrical grid with an integration of power as well as information and communication infrastructure. It is characterized by full duplex flow of energy and information, advanced metering

infrastructure, renewable energy resources, self-healing, active involvement of consumers, and Internet of things.

Wireless Sensor Network: A network comprising of sensor, communication transceivers, memory, processing unit and power supply. Wireless sensor network is useful to convey various parameters such as current, temperature, humidity etc. to the remote monitoring and control unit by using wireless communication technology.

N-Clustering of Text Documents Using Graph Mining Techniques

Bapuji Rao

 <https://orcid.org/0000-0002-2781-9708>

Indira Gandhi Institute of Technology, Sarang, India

INTRODUCTION

Text mining refers to the detection of patterns or similarities in natural language text. For given group of text documents, often the need arises to classify the documents into groups or clusters based on similarity of content. For a small collection, it is possible to manually perform the grouping of documents into specific groups. But to group large volumes of text, the process would be extremely more consumption of time. Therefore, developing a fast and accurate document clustering algorithm is very much helpful for processing of document data sets for clustering.

Clustering is generally studied in data mining problem of text domains. Clustering is an automatic learning technique which aims at grouping a set of objects into Sub-sets or clusters. A clustering can be defined as a grouping of similar objects in the data of similar characteristics. The similarity of characteristics between the objects is measured with the help of a similarity function. The problem of clustering can be very useful in the text domain. Document clustering is extensively used in the areas of text mining and information retrieval. Clustering especially helps of organizing documents in a structural way to improve retrieval and browsing those documents. The study of the clustering problem is related to the applicability to the text domain. Text document clustering is a selection of text documents with the particular word(s)/text(s) present. So each group of text documents called a cluster of text documents of a particular word's presence. Clustering is unsupervised learning it means there is no need of human interference for clustering of documents. In text document clustering, a group of words (texts) is used on a set of text documents for discovering such text documents having with the given set of words (texts). Further such discovered text documents for the given set of words (texts) are grouped into that many clusters of text documents.

Graph mining, is also known as graph-based data mining, is the extraction of meaningful and useful knowledge from a graph representation of data. The most natural form of knowledge that can be extracted from graphs is also a graph. Therefore, the knowledge, sometimes referred to as patterns (or sequence), mined from the data are typically expressed as graphs, which may be sub-graphs of the graphical data.

A Graph $G = (V, E)$ with nodes or vertices in a set of vertices V and a set of edges E . Two nodes $u, v \in V$ are adjacent, if an edge $(u, v) \in E$ exists. The graph representation, that is, a collection of nodes and links between nodes, does support all aspects of the relational data mining process. As one of the most general forms of data representation, the graph easily represents entities, their attributes, and their relationships to other entities. In a bi-partite graph, there are two types of nodes are used. In document clustering, the two types of nodes are document and word. Between the documents and words, the formation of graph is known as document-word bi-partite graph. The relationship between the document-word is the frequency of words present in the related document.

DOI: 10.4018/978-1-7998-3479-3.ch057

BACKGROUND

Document Clustering is also known as Text Clustering is a specific application of text mining and a sub-problem of cluster analyses. If the documents of certain categories are identified and grouped as one cluster, such is called Text Classification Problem. The approach discussed in this chapter is applicable to text documents having characteristics of common word(s) appearances in those text documents for clustering purpose. Finally, each cluster of text documents is represented as a bi-partite graph. In a bi-partite graph, the two types of nodes are document node and word node.

LITERATURE SURVEY

The Scatter-Gather method proposed by authors (Cutting, Karger, Pedersen, & Tukey, 1992) defines the hierarchical organization of documents into coherent categories for systematic browsing of the document collection. It provides a systematic browsing technique with the use of clustered organization of the document collection.

The authors (Aggarwal & Zhai, 2012) define both feature selection and feature transformation methods such as Latent Semantic Indexing (LSI), Probabilistic Latent Semantic Analysis (PLSA), and Non-negative Matrix Factorization (NMF) are used to improve the quality of the document representation and make it more efficient to text clustering. Feature selection is more common and easy to apply in text clustering in which supervision is available for the feature selection process proposed by authors (Yang & Pedersen, 1997). Since the results of text clustering are highly dependent on document similarity. Such cases the concept of term contributed by authors (Liu, Liu, Chen, & Ma, 2003) is applied. So the contribution of a term can be viewed as its contribution to document similarity.

The technique of concept decomposition uses any standard clustering technique has been studied by authors (Aggarwal & Yu, 2001); (Dhillon, & Modha, 2001) on the original representation of the documents. The frequent terms in the centroids of these clusters are used as basis vectors which are almost orthogonal to one another. The documents can then be represented in a much more concise way in terms of these basis vectors. So the condensed conceptual representation allows for enhanced clustering as well as classification of text documents. Therefore, a second phase of clustering can be applied on this condensed representation in order to cluster the documents much more effectively proposed by author (Salton, 1983). Such a method is tested by authors (Slonim & Tishby, 2000) by using word-clusters in order to represent documents.

The non-negative matrix factorization (NMF) technique is a latent space method, and particularly suitable for clustering of text documents proposed by (Xu, Liu, & Gong, 2003). The NMF scheme is a feature transformation method which is particularly used for clustering of documents. Let A be the $n \times d$ term document matrix. To create k clusters from the underlying documents. Then, the non-negative matrix factorization method attempts to determine the matrices U and V by minimizing the following objective function: $J = (1/2) * \|A - U * V^T\|$. The matrix factorization technique is used to determine word clusters instead of document clusters. Just as the columns of V provide a basis which can be used to discover document clusters, just like the use of columns of U to discover a basis which correspond to word clusters. Since document clusters and word clusters are closely related, and it is often useful to discover both simultaneously, and considered as co-clustering. The co-clustering is proposed by (Dhillon, 2001); (Dhillon & Modha, 2001); (Dhillon, Mallela, & Modha, 2003).

Distance-based clustering algorithms are designed by using a similarity function to measure the closeness between the text objects. The most well known similarity function which is used commonly in the text domain is the cosine similarity function proposed by (Aggarwal & Zhai, 2012). These similarity functions can be used in conjunction with a wide variety of traditional clustering algorithms has been studied by authors (Jain & Dubes, 1998); (Kaufman, & Rousseeuw, 2009).

The k-means clustering algorithm also uses a set of k representatives around which the clusters are built. The simplest form of the k-means approach is to start with a set of k seeds from the original set of documents, and assign documents to these seeds on the basis of closest similarity. In the next iteration, the centroid of the assigned points to each seed is used to replace the seed in the last iteration proposed by authors (Aggarwal & Zhai, 2012).

A graph-based approach to document classification is described. The document sets are represented as graph sets where weighted graph mining algorithm is applied to extract frequent sub-graphs. Further the sub-graphs are processed to produce feature arrays (one per document) for classification. Finally the weighted sub-graph mining is used to ensure classification effectiveness and efficient. So that it is most significant of extracting sub-graphs and proposed by authors (Jiang, Coenen, Sanderson, & Zito, 2010).

The word-clusters by authors (Baker & McCallum, 1998) and co-training methods by authors (Nigam, McCallum, Thrun, & Mitchell, 1998) are used in order to improve the classification accuracy of supervised applications with the use of clustering techniques. To enable an effective clustering process, the word frequencies need to be normalized in terms of their relative frequency of presence in the document and over the entire collection of documents. A common representation used for text processing is the vector-space based TF-IDF representation proposed by author (Salton, 1983). Text clustering algorithms are divided into a variety of different types such as agglomerative clustering algorithms, partitioning algorithms, and standard parametric modelling based methods such as the EM-algorithm. An experimental comparison of different clustering algorithms can be seen in articles (Steinbach, Karypis, & Kumar, 2000); (Zhao & Karypis, 2004). The authors (Yang & Pederson, 1997) state that the feature selection is more common and easy to apply in the problem of text categorization in which supervision is available for the feature selection process. Some examples of such methods are Document Frequency-based Selection, Term Strength, Entropy-based Ranking, and Term Contribution. The authors (Hossain & Angryk, 2007) states that the construction of document-graphs from text documents and applies an Apriori paradigm for discovering frequent sub-graphs from them. It represents the English terms in a hierarchical manner and finally construct the document-graphs using WordNet. Each document can be represented as graph of related terms. Then it searches for frequent sub-graphs using graph mining algorithms. It groups documents in the same cluster even if they do not contain common keywords, but possess the same meaning.

A *text* document is a combination of *document* and *term* and these document and term are proposed by authors (Hand, Mannila, & Smyth, 2001); (Salton & Buckley, 1988).

The authors (Ehsan Hosseini-Asl & Jacek M. Zurada, 2014) have made a comparative study of several non-negative matrix factorizations for document clustering for their performance such as accuracy, entropy, purity and computational complexity and residual mean square root error. The author (Vedanayaki, 2014) has studied various graph mining techniques, tools, and issues.

Clustering of m-text documents based on n-words with (1, 2, ..., n) word(s)-wise using graph mining techniques proposed by authors (Rao & Mishra, 2016). It finally creates n-numbers text documents clusters and is shown every cluster as documents-words bi-partite graph.

The authors (Rao & Mishra, 2017) proposed an algorithm for Clustering of m-text documents based on n-words with individual word-wise using graph mining techniques. It finally creates n-numbers text documents clusters word-wise.

Soft document clustering using a novel graph covering approach is proposed by Dörpinghaus, Schaaf, & Jacobs, (2018). The authors adopted graph-theoretical approach for document clustering and its application on a real-world data set.

The authors (Cadot, Lelu, & Zitt, 2018) surveyed seventeen benchmark clustering methods on text dataset. The authors (Maheswari & Sathiaseelan, 2019) proposed enhanced graph fusion method for document clustering.

Let us consider N documents $D = (d_1, d_2, d_3, \dots, d_N)$ and M terms $T = (t_1, t_2, \dots, t_m)$. Each document d_i can be represented as a vector $V_i = (V_{i,1}, V_{i,2}, \dots, V_{i,M})$ in the M -dimensional space R^M . So $V_{i,j}$ represents a measure of association of the term t_j with the document d_i . The value of $V_{i,j}$ is 0 if the document d_i does not contain the term t_j and otherwise it is a nonzero value which is the indication of frequency. In Boolean representation, $V_{i,j} = 1$ if the term t_j appears in the document d_i ; otherwise $V_{i,j} = 0$. Based on this approach, a text is simply modelled as a *document-term frequency matrix* which is depicted in “Figure 1”. To represent the *document-term frequency matrix* for a set of five documents $\{D_1, D_2, D_3, D_4, D_5\}$ and four terms $\{T_1, T_2, T_3, T_4\}$ is of order 5×4 . Assume the terms are T_1 =Economy, T_2 =Cinema, T_3 =Election, T_4 =Admission. Document D_2 is a vector $(4, 7, 9, 13)$ represents as the second row in the matrix, in which the term Economy appears 4 times, Cinema appears 7 times, Election appears 9 times, and Admission appears 13 times, respectively.

Figure 1.

		Terms			
		T ₁	T ₂	T ₃	T ₄
Documents	D ₁	10	6	8	12
	D ₂	4	7	9	13
	D ₃	20	30	15	40
	D ₄	7	10	3	6
	D ₅	5	8	9	2

This chapter is about the proposal of an algorithm, **n-WDCluster** to cluster of m-text documents with the input of n-words, which produces two sets of clusters namely individual word-wise cluster and (1, 2,, n) word(s)-wise cluster.

PROPOSED METHOD

The author propose a method for clustering of only text documents (extension name “.TXT”) word-wise as well as (1, 2,, n) word-wise. A set of m-document names having different extension names are given to the model where it only selects the documents with extension name “.TXT”. The selection of text documents is depicted in “Figure. 2(a)”. On the selected text documents, n-words are applied for

creation of two types of clustering of text documents. The 1st clusters of text documents are formed based on individual word-wise i.e. n -numbers of text documents clusters are formed. Similarly the 2nd clustering of text documents are based on $(1, 2, 3, \dots, n)$ word-wise i.e. again n -numbers of text documents clusters are formed having $(1, 2, 3, \dots, n)$ number of word(s) and depicted in “Figure. 2(b)”.

In case of individual word-wise clusters, the method creates a documents-words frequency matrix of order $m \times n$. By using the frequency matrix, the text documents clustering of individual words are created. Hence there are n -numbers of clustering of documents are formed for the n -numbers of words.

Similarly in case of $(1, 2, \dots, n)$ word-wise clusters of text documents, the documents-words frequency matrix is translated into un-oriented documents-words incidence matrix where all the non-zeros are replaced with 1s. By taking the help of un-oriented documents-words incidence matrix, the $(1, 2, \dots, n)$ word-wise clusters of text documents are formed. Here it too forms n -clusters since there are n -numbers of words. The first cluster of text documents is the presence any one word from n -words. Similarly the n^{th} cluster of text documents is the presence of all n -words in the clustered text documents. Finally these n -clusters are shown as bi-partite graphs since there are two types’ nodes used namely

Figure 2.

words and documents.

PROPOSED ALGORITHM

Algorithm n -WDCluster() [Algorithm Convention (Horowitz, Sahni, & Mehta, 2013).]

// Global Declarations

Document.Txt: Text file to contain 'm' documents name.

Word.Txt: Text file to contain 'n' words.

Document[m]: To assign 'm' text documents name with extension ".Txt".

Word[n]: To assign 'n' words.

Frequency[m][n]: Documents-Words matrix to contain frequencies.

```
{
// to open the file "Document.Txt"
open("Document.Txt");
// to read total number of documents
read(m);
// to pick text documents with extension name ".Txt" and store in the array
Document[ ]
i:=0;
while(not EOF())
do
{
// to read text document name from file "Document.Txt"
read(DocumentName);
Extension:=Get_Extension_Name(DocumentName);
if(Extension=".Txt")
{
i:=i+1;
Document[i]:=DocumentName;
}
}
close("Document.Txt");
// to assign the actual number of ".Txt" documents i.e., 'i' in 'm'
m:=i;
// to open the file "Word.txt"
open("Word.txt");
// to read total number of words
read(n);
i:=1;
while(not EOF())
do
{
// to read words from file "Word.txt"
read(Word[i]);
i:=i+1;
}
close("Word.Txt");
DocWord_MatrixCreation();
// to write the Document-Word Frequency matrix in the file "WIMatrix.Txt"
UIMatrix_Write("WIMatrix.Txt");
// text documents clustering word-wise
```

```
Cluster_Formation_Word();  
// to replace all non-zeros of Frequency[m][n] with 1  
for i:=1 to m do  
{  
  for j:=1 to n do  
    if(Frequency[i][j]≠0) then Frequency[i][j]:=1;  
  }  
// to write the Un-Oriented Documents - Words Incidence Matrix in the file  
"UIMatrix.Txt"  
  UIMatrix_Write("UIMatrix.Txt");  
// text documents clustering (1, 2, ....., n)word-wise  
  Cluster_Formation();  
}
```

PROCEDURE FOR CREATION OF DOCUMENT-WORD MATRIX

Procedure DocWord_MatrixCreation()

flag[m]: To assign the files status i.e. availability or not in the disk

```
{  
  // to check the availability every file names'  
  for i:=1 to m do  
  {  
    flag[i]:=0;  
    // to open the ith text document for reading  
    open(Document[i]);  
    if(Not_Found(Document[i])) then flag[i]:=1;  
    close(Document[i]);  
  }  
  status:=0;  
  for i:=1 to m do  
  {  
    if(flag[i]=1)  
    {  
      write(Document[i],"Not Found");  
      status:=1;  
    }  
    flag[i]:=0; //reassignment  
  }  
  if(status=1) then write("No Text Document Clustering");  
  else // status is OK
```

```

{
  for i:=1 to m do
  {
    // to open the ith text document
    open(Document[i]);
    st:=" ";
    // read a character from ith text document and assign to 'ch'
    read(ch);
    while(not EOF())
    do
    {
      if(ch=space or ch='\n')
      {
        // to check whether the 'st' word is present in Word[] array or
not
        for j:=1 to n do
        {
          if (Word[j]=st) then DocWord[i][j]:=1;
          else DocWord[i][j]:=0;
        }
        st:=" ";
      }
      else st:= st + ch;
      // read character-wise from ith text document and assign to 'ch'
      read(ch);
    } //while close
    close(Document[i]);
  } // for close
} //else close
}

```

PROCEDURE TO WRITE WORD-WISE CLUSTERING OF TEXT DOCUMENTS IN FILES

Procedure Find_Documents_Word(Frequency, Column)

Frequency [m][n]: Documents-Words matrix to contain frequencies.

Column: Column index of word in the matrix Frequency[][].

DIndexWFre[][2]: To assign the detected frequencies document index and its frequency.

```

{
  j:=1;

```

```
for i:=1 to m do
{
    if(Frequency[i][Column]!=0)
    {
        DIndexWFre[j][1]:= i; // document index
        DIndexWFre[j][2]:= Frequency[i][Column]; // word frequency
        j:=j+1;
    }
}
FileName:=Word[Column]+".Txt";
// to open the file 'FileName' for writing purpose
open(FileName);
// to write in the file 'FileName'
Write("Cluster of Documents of Word"+Word[Column]);
for i:=1 to j do
    Write(Document[DIndexWFre[i][1]] + " " +DIndexWFre[i][2]);
// to open the file 'FileName'
close(FileName);
}
```

PROCEDURE FOR CREATION OF WORD-WISE TEXT DOCUMENTS CLUSTERING

Procedure Cluster_Formation_Word ()

```
{
    for i:=1 to n do // n no. of words
        Find_Documents_Word(Frequency, i);
}
```

PROCEDURE TO WRITE (1, 2, 3,, N) WORD(S)-WISE CLUSTERING OF TEXT DOCUMENTS IN FILES

Procedure DetectDocuments(DocWord, words, twords)

DocWord [m][n]: Document-Word Un-Oriented matrix.

words: Actual number of words.

twords: Number of words used for cluster.

Cluster[m]: To assign the text documents index values.

```

{
  for i:=1 to m do
  {
    count:=0;
    for j:=1 to words do
      if(DocWord[i][j]=1) then count:=count+1;
    if(count=twords)
    {
      k:= k+1;
      //to assign text document index
      cluster[k]:=i;
      flag:=1;
    }
  }
  if(flag=1)
  {
    FileName:="CD"+twords+".Txt";
    // to open the file 'FileName' for writing purpose
    open(FileName);
    // to write cluster of documents with 'tword' word(s) presence in the file
    'FileName'
    for i:=1 to nw do
      write(Word[i]);
    // to write text document names and its presence as value 1 in the file
    'FileName'
    for i:=1 to k do
    {
      write(Document[cluster[i]]);
      for j:=1 to nw do
        write(DocWord[Cluster[i]][j]);
      }
    // to close the file 'FileName'
    close(FileName);
  }
  else
    write("No Documents Clustering");
}

```

PROCEDURE FOR CREATION OF (1, 2,....., N) WORD(S)-WISE CLUSTERING OF TEXT DOCUMENTS

Procedure Cluster_Formation ()

```
{  
  for i:=0 to (n-1) do    // n no. of clusters  
  {  
    DetectDocuments(Frequency, n, n-i);  
  }  
}
```

PROCEDURE TO WRITE BOTH WEIGHTED AND UN-ORIENTED INCIDENCE MATRICES IN FILES

Procedure UIMatrix_Write(FileName)

```
{  
  // to open the file 'FileName' for writing purpose  
  open(FileName);  
  
  for i:=1 to n do  
    write(Word[i]); // to write words in 'FileName'  
  for i:=1 to m do  
  {  
    write(Document[i]); // to write text document names in 'FileName'  
    for j:=1 to n do  
      write(Frequency[i][j]); // to write frequencies in 'FileName'  
    }  
    close(FileName); // to close the file 'FileName'  
}
```

PROCEDURE TO VERIFY THE PRESENCE OF WORD IN THE TEXT DOCUMENT

Procedure Verify(Row, String)

Row: Row index of word.

String: Word to verify in the array Word[.].

```
{  
  for i:=1 to n do  
  {  
    st1:=Word[i]+".";  
    st2:=Word[i]+",";"  
    st3:=Word[i]+";";
```

```
// to verify word 'String' of Document[Row] for all words of array Word[]
if(String=Word[i] or String=st1 or String=st2 or String=st3) then
    Frequency[row][i]:=Frequency[row][i]+1;
}
}
```

PROCEDURE TO CREATE DOCUMENTS-WORDS FREQUENCY MATRIX

Procedure DocWord_MatrixCreation()

flag[m]: To assign the files status i.e. availability(0) or not(1) in the disk.

```
{
    // to check the availability of every file name
    for i:=1 to m do
    {
        flag[i]:=0;
        // to open the ith text document for reading purpose
        open(Document[i]);
        if(Not_Found(Document[i])) then flag[i]:=1;
        close(Document[i]);
    }
    status:=0;
    for i:=1 to m do
    {
        if(flag[i]=1)
        {
            display(Document[i],"Not Found");
            status:=1;
        }
        flag[i]:=0; // reassignment
    }
    if(status=1) then display("No Text Document Clustering");
    else // status is OK
    {
        for i:=1 to m do
        {
            // to open Document[i] for reading purpose
            open(Document[i]);
            st:=" ";
            // to read a character from Document[i] and assign to ch
            read(ch);
        }
    }
}
```

```

while(not EOF())
do
{
    if(ch=space or ch='\n')
    {
        // to verify word 'st' in Word[] array
        Verify(i, st);
        st:=""
    }
    else st:= st + ch;
    // to read a character from Document[i] and assign to ch
    read(ch);
} // while
close(Document[i]);
} // for
} // else
}

```

The proposed algorithm, ***n*-WDCluster** has three phases. The Phase-I reads two datasets namely “*Word.Txt*” and “*Document.Txt*”, which contains *n*-words and *m*-text document names respectively. First the dataset file “*Document.Txt*” is opened for reading. It assigns the number of documents to the variable *m* and all *m*-text document names to the array, Document[*m*]. Secondly it opens the second dataset file “*Word.Txt*” for reading purpose. It assigns the number of words to the variable *n* and all *n*-words to the array, Word[*n*]. So Phase-I is all about reading of data i.e. *n*-words and *m*-text document names respectively.

The Phase-II for calling of three procedures namely DocWord_MatrixCreation(), UIMatrix_Write(), and Cluster_Formation_Word(). The 1st procedure is to detect the availability of text documents in the disk. Based on its availability status, it checks all its words with the *n*-words available in the array Word[*n*] by calling the procedure Verify(). If the word of text document is found in the array Word[*n*] then it updates the corresponding word in the matrix Frequency[*m*][*n*]. By calling the 2nd procedure, the frequency matrix is written in the file called “*WIMatrix.Txt*”. The 3rd procedure is called for writing all the *n*-clusters formed word-wise in *n*-text files by calling the procedure Find_Documents_Word(). So Phase-II is about the writing of frequency matrix and *n*-clusters word-wise in (*n*+1) text files.

The Phase-III first converts the frequency matrix Frequency[*m*][*n*] to Boolean matrix by replacing all non-zeros with 1s, which is considered as the un-oriented documents-words incidence matrix. The procedure UIMatrix_Write() is called for writing the Boolean matrix Frequency[*m*][*n*] in the text file called “*UIMatrix.Txt*”. Then the procedure Cluster_Formation() is called which in turn calling the procedure DetectDocuments() for writing (1, 2, 3,, *n*) word-wise cluster in *n*-text files. So Phase-III is about the writing of un-oriented incidence matrix and (1, 2,, *n*) word(s)-wise clusters in (*n*+1) text files.

EXPERIMENTAL RESULTS

Example

Two dataset files namely “*Document.Txt*” and “*Word.Txt*” are created for the above proposed algorithm ***n*-WDCluster**. In “*Document.Txt*”, the 1st row has the total number of documents and the 2nd rows onwards have the document names. Similarly in “*Word.Txt*”, the 1st row has the total number of words and the 2nd rows onwards have the unique word names. When input these two datasets to the experiment, it opens both the dataset files. The details are read from these two dataset files and assigned to the variable *n*, the array Word[*n*], the variable *m*, and the array Document[*m*] respectively. It reads every document names

Figure 4.

from the array Documents[m] and only selects the document file with extension name “.Txt”. Since the algorithm has to clustering of text documents with extension name “.Txt”. The “Document.Txt” has 74 numbers of documents with different extension names. The algorithm only selects 48 numbers of text documents with extension name “.Txt” and stored in the array Documents[m] having document names 1.Txt, 2.Txt, 3.Txt,....., and 48.Txt respectively. The procedures DocWord_MatrixCreation() and Verify() are responsible of creation of matrix Frequency[m][n]. The procedure UIMatrix_Write() writes the matrix, Frequency[m][n] in a text file called “WIMatrix.Txt” which is considered as the Documents- Words Frequency matrix and depicted in “Figure 3”.

The procdure Cluster_Formation_Word() creates the Documents-Words frequency matrix, Frequency[m][n]. Here the order of Documents-Words frequency matrix is 48x10 since there are 48

Figure 6.

numbers of text documents and 10 numbers of words respectively. Using Documents-Words frequency matrix, $\text{Frequency}[m][n]$, it started creation of word-wise n -clusters of text documents. In this example the 10 words are {Browser, Database, Network, E-Mail, HTML, Internet, Protocol, TCP/IP, Web, Rule}. Hence 10 numbers of clusters are formed and written in text files viz. “Browser.Txt”, “Database.Txt”, “Network.Txt”, “E-Mail.Txt”, “HTML.Txt”, “Internet.Txt”, “Protocol.Txt”, “TCP/IP.Txt”, “Web.Txt”, and “Rule.Txt” respectively.

After formation of word-wise clusters, the frequency matrix, $\text{Frequency}[m][n]$ is converted into Boolean matrix, which is considered as the un-oriented documents-words incidence matrix depicted in “Figure 5”. Then the procedure `Cluster_Formation()` is called which in turn calling the procedure `DetectDocuments()` for creation of 1-word appearance cluster, 2-words appearance cluster, 3-words appearance cluster, 4-words appearance, 5-words appearance, 6-words appearance, 7-words appearance, 8-words appearance, 9-words appearance, 10-words appearance and written in 10 text files viz. “CD1.Txt”, “CD2.Txt”, “CD3.Txt”, “CD4.Txt”, “CD5.Txt”, “CD6.Txt”, “CD7.Txt”, “CD8.Txt”, “CD9.Txt”, and “CD10.Txt” respectively.

Results of Word-Wise Document Clustering

By using “Figure 3”, the author represent graphically as Documents-Words weighted bi-partite graph and depicted in “Figure 4”. There are two types’ of nodes viz. Documents and Words. The edge between the Documents and the Words indicate the frequency of words in the related documents.

Results of (1, 2,....., n) Word(s)-Wise Document Clustering

By using “Figure 5”, the author represents graphically as Documents-Words bi-partite graph and depicted in “Figure 6”. The two types of nodes are Documents and Words. The edge between the Documents and the Words indicate the presence of words in the related documents.

The algorithm was written in C++ and compiled with *DevC++*. The experiment was run on Intel Core I5-3230M CPU + 2.60 GHz Laptop with 4GB memory running MS-Windows 7.

The authors (Dhillon, & Modha, 2001) studied vector space models of large document collections. These models generally have very high-dimensional and sparse, which require unique computational and statistical challenges.

The document clustering using word clusters is a double-clustering procedure which follows two stage processes. The first procedure finds the word-clusters. In second procedure the document clusters are obtained by using the word-clusters is proposed by (Slonim & Tishby, 2000).

The authors (Xu, Liu, & Gong, 2003) proposed a novel document clustering method based on the non-negative factorization of the term document matrix of the given document corpus. The non-negative matrix factorization (NMF) captures the base topic of a particular document cluster, and each document is represented as an additive combination of the base topics. The cluster membership of each document can be easily determined by finding the base topic with the document’s largest projection value.

The authors (Rege, Dong, & Fotouhi, 2006) proposed a novel idea of modelling set of documents having similar characteristics as a bipartite graph between documents and words. So that simultaneous clustering of documents and words are formed. Then the authors use a new spectral co-clustering algorithm to partition the co-clustering into individual clusters of documents and words.

The main problem in contingency table analysis is co-clustering i.e. simultaneous clustering exist at rows and columns. The authors (Dhillon, Mallela, & Modha, 2003) proposed a co-clustering algorithm that tries to preserve mutual information by twining both the row and column clustering at all stages.

In text classification using graph mining based feature extraction is proposed by (Jiang, Coenen, Sanderson, & Zito, 2010). It represents nodes as sentence, and the internal structures of noun (NP), verb (VP) and prepositional phrases (PP) are represented by triangles. The part of speech (POS) is represented as circle, token as rectangles, and semantic as ovals. This technique is about to extract frequent sub-graphs.

CONCLUSION

The proposed algorithm, n -WDCluster clusters only text documents after input of m -documents of various extension name. The algorithm only selects documents with extension name “.Txt” from m -documents. These m -text documents are clustered on the input of n -words. The algorithm successfully forms n -numbers of cluster of two formats. The first format of n -clusters is formed word-wise. Similarly the second format of n -clusters is formed $(1, 2, \dots, n)$ word(s)-wise. The proposed algorithm, n -WDCluster was implemented using C++ programming with the datasets depicted in the “Figure 3”. The author has observed satisfactory results of creation of *ten* numbers of word-wise clusters as well as ten numbers of $(1, 2, \dots, 10)$ word(s)-wise clusters of text documents. Here the clustering of document-word is one type of bi-partite graph since two types of nodes such as document and word are used. The algorithm was written in C++ language. The experiment was run on Intel Core I5-3230M CPU + 2.60 GHz Laptop with 4GB memory running MS-Windows 7 and observed satisfactory results.

FUTURE RESEARCH DIRECTION

This proposed algorithm of this chapter clusters text documents with extension name “.TXT” word-wise. The future work lies with clustering of documents containing text and images with any extension name image-wise.

KEY TERMS AND DEFINITIONS

Bi-Partite Graph: A graph with two types of nodes viz. Word node and Document node. The relationship between the word and document is an edge which is the indication of word in the related document.

Cluster: The set of related documents which consist of a particular word.

Documents-Words Frequency Matrix: A matrix which consists of only the words frequency in documents.

Un-Oriented Documents-Words Incidence Matrix: A matrix consists of only 1 which is the indication of presence of word in documents.

Characterization of Elevated Tumor Markers in Diagnosis of HCC Using Data Mining Methods

INTRODUCTION

The process of identifying patterns in huge datasets comprising methods such as machine learning, statistics, and database system can be considered data mining. It is a multidisciplinary field in computer science, and it excerpts knowledge from the massive data set and converts into comprehensible format. The Medical environment is rich in information but weak in knowledge. Medical systems contain wealth of data which require a dominant analysis tool for determining concealed association and drift in data. The health care condition that comprehends to liver disorder is termed as Liver disease. Liver disorder leads to abrupt health status that precisely governs the working of liver and intern affecting other organs in the body. Data mining classification techniques like Decision Tree, Linear Discriminant, and SVM Fine Gaussian and Logistic Regression algorithms are applied.

BACKGROUND

Hepatocellular Carcinoma (HCC) is an abnormal condition of human liver which is diagnosed at a very advanced stage. The disease is liver disorder which can be predicted after series of clinical and laboratory and imaging studies. Hepatocellular carcinoma is the most malignant tumors which is the major cause of death and requires to be treated at early stage. Benign tumors do not lead to cancer but malignant tumors lead to cancer. The lab investigation accords to austerly of the disease in liver together with physiology of the condition. The laboratory studies incorporate persistence of electrolytes, Complete Blood Count, Liver Function Tests, International Normalized Ratio (INR), partial thromboplastic time (PTT) and AFP (Alpha-Feto Protein) tests. Alpha-fetoprotein (AFP) is considered as one of the tumor markers of HCC. AFP is produced by tumors or by regenerating hepatocytes, but not all tumors produce AFP. The elevations in AFP level greater than 400ng /DL in proper clinical context and appropriate radiologic findings marks the diagnosis of HCC. Increased AFP along with proper imaging studies is considered diagnostic of HCC. The medical imaging techniques like USG (Ultrasonography), CT (Compute Tomography) scan, and MRI (Magnetic Resonance Imaging) creates an interior visualization of the body. Surgical resection or ablation cannot be planned with the anatomic detail obtained from ultrasonography. The lesions are not detected significantly. Although CT scan is highly accurate compared to ultrasonography,

DOI: 10.4018/978-1-7998-3479-3.ch058

it may miss some of small lesions. MRI is an excellent method to characterize HCC. HCC demonstrates various features which is clearly differentiated in MRI scan. Patients with lesions larger than 1 to 2 cm are recommended for biopsy since they are predicted to be under risk of malignancy. The decision on resection, transplantation and ablative therapy is taken based on the biopsy result.

According to the literature survey advanced hepatocellular carcinoma was treated with Sorafenib molecular target drug which increased the survival time of the patient with 3 to 4 months (Gomaa W., 2017). Presence of Hepatitis C virus and non-alcoholic fatty liver also contributed to liver disorder. Researchers developed a framework considering the imaging studies and found that imaging studies alone was not sufficient for efficient diagnosis of the disease. Artificial Immune Systems and Artificial Neural Network algorithms were applied on laboratory parameters. Artificial Neural Network gave the better result (Shane Dixon & Xiao-Hua Yu, 2016). Data mining algorithms support vector machine and back propagation algorithm was applied on the liver function test attributes. Support vector machine gave best results. Micro array analysis was used as molecular biology approach where the result was affected by diet, age, and ethnicity (Sumedh Sontakke, 2017). Clinical decision support systems support physicians to carry out meticulous prediction of the disease. The Volume of the dataset, and attributes present in the dataset along with the competence and deficiency of the classifiers contributes to deal with medical issues (Ahmed J. Aljaaf, 2015). A cancer prediction system provides warning to the patients thereby reducing the cost and saving time. Validation of the system is done by comparing the predicted results with the previously available medical record of the patient (K.Arutchelvan, 2015). The study of hepatitis dataset and its contribution to Hepatocellular carcinoma. Machine learning algorithms along with feature selection algorithms were applied on the hepatitis dataset. K-fold cross validation was implemented where diverse number of fold were applied and performance was analyzed (Tri Astuti, 2015). The use of logistic regression and artificial neural network models for biomedical data classification was presented by the researchers. The study gave the conclusion that no single algorithm can outperforms all other algorithms. The result depends on the kind of data and cases (Stephan Dreiseitla, 2003). Eleven data mining classification algorithms were applied to the datasets and the performance of all classifiers are compared against each other in terms of accuracy, precision, and recall. Several investigations have also been carried out to improve performance of the classification models. Finally, the results shown promising methodology in diagnosing liver disease during the earlier stages (Sina Bahramirad, 2013). Abnormal LFT result not only mean that the problem is pertaining to liver always, it may also indicate abnormalities in other organs. To overcome this, researchers came out with a prediction model called Algorithm for Liver Function Investigations (ALFI), which gave a decision support tool incorporating a clinical prediction rule that facilitated for the management of patients in primary care. The C-Statistic technique was used for the study (David J. McLernon, 2012). A framework was proposed based on ultrasound images for classifying liver fibrosis. Deep features were learnt via transfer learning and Visual Geometry Group neural network (VGGNet). Fully connected network (FCNet) classifier was trained in order to predict the normal, early stage and late stage fibrosis liver status (Dan Meng L. Z., 2017). Each stage of liver cancer is diagnosed depending on extent to which liver is damaged. To determine the degree of liver damage at four different stages, a KNN based intelligent computational method was presented. The accuracy of the classification was compared with linear discriminant analysis, diagonal linear discriminant analysis, quadratic discriminant analysis, diagonal quadratic discriminant analysis classifiers and classification and regression trees (Singh & Pandey, 2016).

Based on the literature survey, the authors have used both statistical and computational techniques for diagnosis of Hepatocellular Carcinoma. The authors in the computational methods used laboratory parameters and imaging studies, and the authors in statistical techniques considered tumor markers.

Diagnosis of Hepatocellular Carcinoma requires the study of tumor markers along with laboratory parameters. The chapter focusses on study of tumor marker along with liver function test attributes.

FOCUS OF ARTICLE

Healthcare domain generates huge data which is very complex and vast. The data contains many hidden parameters and patterns which is useful in predicting the disease. Data mining helps in recognizing these hidden patterns and arriving at the diagnosis of the disease. In this chapter the authors are concentrating on HCC tumor makers. The aim of the study is to predict the presence of tumor markers and their contribution in HCC Progression using data mining techniques. The presence of tumor is initially detected considering elevated AFP ($>400\text{ng/DL}$) as tumor marker. The tumor marker along with other attributes of Liver Function Test helps in determining the aggressiveness of cancer and response to certain drugs (Hall, 2012). The proposed study concentrates on the contribution of tumor markers in diagnosing the HCC at the earlier stage there by increasing the survival time of the patient. The survival time of the patient is diagnosed based on the elevation in tumor marker. The chapter focusses on application of data mining techniques on the LFT attributes along with tumor marker that contributes for HCC Progression. As the HCC progresses, the tumor spreads in multiple lobules inside the liver in form of hepatocellular cells and further multiplies and grows to form large tumor. The below figure gives shows the existence of hepatocellular cells inside the liver. The histopathological images of the liver make it easy to differentiate the abnormality in the liver and the extent to which liver is damaged due to HCC.

Figure 1. Hepatocellular Carcinoma cells in the liver

The standard threshold values of each attribute that are considered in this chapter is given in below table.

The diagnosis of HCC in the previous studies is based on the blood test results, ultrasound imaging, and genomic expression. The imaging studies like CT scan, Ultrasound scanning were not sufficient in identifying the number of lesions in the liver (Dan Meng L. Z., 2017). The Prognosis of liver disease is the reflection of both tumor characteristics like tumor size, location, and tumor biology along with the degree of underlying resection. Statistical analysis techniques are been used by the researchers and they

Table 1. Threshold values of LFT attributes

Attributes	Minimum – Maximum Value
ALP	15-129 IU/L
SGOT_AST	5-34 units
SGPT_ALT	0-40 Units
TP	6.0-8.3 gm/dl
Serum_ALB	3.2-5.0 gm/dl
Serum_GLB	2.3-3.5 gm/dl
AG_Ratio	1.5 - 2.5 gm/dl
Total_Bilirubin	0.2-1.0mg/dl
GGT	15.0-85.0 IU/L
Direct_Bilirubin	0.0-0.2 mg/dl
Indirect_Bilirubin	up to 0.6mg/dl
SerumCreatinineCT	Male: 0.7-1.2, Female: 0.5-0.9
AFP	<10ng/mL

have not yielded an efficient prediction due to various reasons, but the accuracy of their results was not measured (Heba Ayeldeen O. S., 2015). The elevation in tumor markers contributes to predicting the survival time of the patient. The chapter focuses on contribution of tumor markers in diagnosing HCC at earlier stage. The tumor marker test Alpha -Feto Protein test is considered to analyze the presence of HCC.

SOLUTIONS AND RECOMMENDATIONS

Hepatocellular Carcinoma is diagnosed only in its advance stage. The diagnosis requires both bio-chemistry test and tumor marker test. The bio-chemistry test is the liver function test (LFT) that is done out of blood sample. The deviation in parameters of LFT along with the tumor marker confirms the presence of HCC. The stage of HCC is determined based on size of liver, number of lesions found and their size. In the proposed work, the authors consider the tumor marker Alpha-Feto Protein (AFP) level along with the LFT attributes to predict the presence of HCC. The dataset has attributes such as, Age, Gender, ALP (Alkaline Phosphate), Serum_GLB (Serum Globulin), SGOT_AST (Serum glutamic oxaloacetic transaminase_aspartate aminotransferase), Serum_ALB (Serum Albumin), SGPT_ALT (Serum glutamic pyruvic transaminase_alanine aminotransferase), TP (Total Protein), AG_Ratio (Albumin Globulin Ratio), Total_Bilirubin, GGT (gamma-glutamyl transferase), Direct_Bilirubin, Indirect_Bilirubin, SerumCreatinineCT, and AFP (Alfa-Feto Protein).

The dataset consists of details of 250 patients who are predicted of Hepatocellular Carcinoma (HCC). The data is collected from one of the oncology centers. The dataset is divided into 70% training set and 30% test set.

Data mining classification analysis techniques like Decision Tree, Logistic Regression, Naïve Bayes and Support Vector Machines (SVM) algorithms are applied on the dataset. The deviation from normal values of SGPT_ALT, SGOT_AST along with raised values in AFP along with the CT scanning resulted in prediction of Hepatocellular Carcinoma. SGPT_ALT correlates with explicit hepatocellular disease.

ALP correlates to tumors and biliary diseases. The elevated values of ALT, AST and AFP is considered as markers for diagnosing HCC progression.

The decision tree classifier gave the highest accuracy of 0.91, while Logistic Regression, Naïve Bayes and SVM gave 0.81, 0.90, and 0.89 respectively. Data mining R tool is used for the analysis. The following table gives the performance of algorithms with respect to accuracy and other factors.

Table 2. Performance of Algorithms on the dataset

Algorithm	Accuracy in %	No. of True Positives	No. of True Negatives	No. of False Positives	No. of False Negatives	Misclassification Rate
Decision Tree	91	89	2	0	9	0.09
Naïve Bayes	90	89	1	0	10	0.1
SVM	89	89	0	0	11	0.11
Logistic Regression	81	80	1	9	10	0.19

The sensitivity is when the result is actually yes and when it is predicted yes, specificity is when actually no and predicted no. The dataset contains many false positives which means that the patients actually does not have disease but its predicted yes which may cost money and time for patients. The false negatives predicts no when the patient actually have the disease which may cost patient life. Decision Tree gave the maximum accuracy, zero false negatives and low misclassification rate compared to Naïve Bayes, SVM and Logistic Regression.

The figure 2 gives confusion matrix obtained from dataset. Decision tree obtained while plotting the tumor marker AFP is given in figure 3.

Decision Tree

Figure 3. Decision tree showing AFP

The above figure 3 shows decision tree with tumor marker along with LFT attributes. Decision tree CART is used for the analysis since the dataset contains both numerical and categorical values. The Decision tree formed explains that the tumor marker AFP is more significant than other attributes, along GGT level.

Figure 4. Decision tree showing all attributes except AFP

Decision Tree

The above figure shows the decision tree when tumor marker AFP is excluded. SGPT_ALT is the next significant attribute after AFP to diagnose HCC.

The elevation of AFP along with the LFT attributes ALT and ALP contributed in diagnosis of HCC. The attributes in the dataset ALP, SGOT_AST, SGPT_ALT, are the enzymes present in liver and are considered to be significant parameters in predicting Liver disorder. The data mining algorithms, Decision Tree, Naïve Bayes, SVM and Logistic regression were applied on the dataset. Decision tree gave the highest accuracy 91% with sensitivity 0.9 and specificity equal to 1.

FUTURE RESEARCH DIRECTIONS

Further work can be carried out by considering the parameters from the imaging studies and other confirmative tests. The confirmative test such as FNAC (Fine Needle Aspiration Cytology) along with the AFP test can confirm the presence of HCC and the stage of the disease. The diagnosis of HCC also includes other tumor markers such as DCP (Des-gamma-carboxy prothrombin), GP73 (Golgi protein 73) and AFP-L3. These markers can be further explored to arrive at accurate prediction. More research can be carried out by applying various machine learning algorithms.

CONCLUSION

Hepatocellular carcinoma being one of the deadly diseases and major cause of death world-wide is diagnosed in its advance stages most of the time. The research work was carried for development of organized structure to find out the presence/ absence of HCC disease among the patients using the reports and symptoms collected from them. The generated data was structured and stored in the necessary format, clinical and operational data was configured. The work helped in finding strengths and weakness of various previous work and building focus on unexplored parameters of HCC. The prediction of disease involves various tests and analysis considering various parameters. The authors have considered Liver Function Test along with the tumor marker AFP. The researchers found that elevation of AFP along with the LFT attributes ALT and ALP contributed in diagnosis of HCC. Decision Tree, Naïve Bayes, SVM and Logistic regression are applied on the dataset. Decision tree gave the highest accuracy 91% with sensitivity 0.9 and specificity equal to 1.

KEY TERMS AND DEFINITIONS

AFP: Alpha feto protein (AFP) is one of the standard tumor markers in detection of Hepatocellular Carcinoma. The test is done by drawing blood from the patient and measuring the AFP levels.

Benign Tumors: A tumor is an abnormal mass of tissue. Benign tumors are not cancerous and cannot spread. A benign tumor remains constant and do not grow, and they do not return after removing.

Confusion Matrix: The performance of the classification model is given by confusion matrix in the form of table. The dataset is a test set whose true values are known.

CT Scan: Computed tomography (CT) scan is a type of imaging study of human body. Computers and rotating X-Ray machines provides comprehensive information regarding the bold vessels, bones in various parts of body and blood vessels.

FNAC: A symptomatic method where a small chunk of tissue is sucked by inserting a needle into body and examined with the help of microscope is called FNAC (Fine Needle Aspiration Cytology). FNAC is a diagnostic procedure where a needle is inserted into the body and a small amount of tissue is sucked for examination under a microscope. If any suspicious lump is found, or if any abnormality is detected in imaging tests, the FNAC is performed.

LFT: Liver function test (LFT) is a bio-chemistry test which is done to determine the health of the liver by measuring various enzymes present in the blood.

Malignant Tumors: Malignant tumors are unwanted mass of tissue, which is cancerous. It spreads, multiplies and gets worse damaging the organs.

MRI: The MRI (magnetic resonance imaging) creates a structure and cross- sectional image of the internal organs using a large magnet, radio waves and computer.

Screening: Early diagnosis of any disease is essential to avoid worst situations. Screening is a preventive measure to identify probable health problem without having any symptoms or sign of the disease.

Sensitivity: If the test diagnoses the patient with disease as having the disease, then it is referred to as sensitivity.

Specificity: If the test diagnoses the patient without disease as not having disease, then it is referred to as specificity.

Ultrasonography: The motion of the organs and structures in the body are captured briskly using ultrasound images. The growth of alien objects in the organs like breasts, thyroid gland, limbs and lymph nodes can be recognized using ultrasound images.

Designing a Concept–Mining Model for the Extraction of Medical Information in Spanish

INTRODUCTION

In recent years, the automatic processing of biomedical information has been benefited from advances made by data and text mining. An example of this advance is the book edited by Ananiadou & McNaught (2006), who give a special relevance to create and use tools capable to extract information from large collections of documents, particularly **PubMed** (www.ncbi.nlm.nih.gov/pubmed/). In fact, given this dimension, Pubmed is the most important repository for obtaining biomedical data, what has motivated the generation of different projects related to computational linguistics such as the **Corpus Genia** (www.geniaproject.org), the **MEDIE** search engine (www.nactem.ac.uk/medie/), or the **Open Biological and Biomedical Ontology Project** (<http://obofoundry.org/>), focused on the development of ontologies that provide an organized knowledge system in biomedicine.

In line with these projects, it is exposed here a method for performing a concept mining on biomedical documents in Spanish. This model is based on the automatic extraction of definitional contexts (or DCs), according to the framework developed by Sierra *et al.* (2008), Sierra (2009), Aguilar & Acosta (2016), as well as Aguilar *et al.* (2016). Our model has been sketched having in mind the following objectives:

- The linguistic analysis of definitional contexts identified in biomedical texts in Spanish.
- The creation of a linguistic corpus in Spanish that is representative for the biomedical area.
- The use of stochastic methods in order to provide empirical evidence to validate in linguistic analysis previously performed.

These objectives allow to establish a set of concrete tasks that can be implemented as modules for a mining system, concretely:

- a) Extraction of terminological information: this one focuses on establishing a chain of text processing, which considers: (i) the selection, tokenization and syntactic annotation of a Spanish corpus in medicine; (ii) the identification of uni/multiword terms using a hybrid method (Acosta, Aguilar & Infante, 2015).
- b) Identification of lexical relations: taking advantage of the term extraction and linking them to their definitions, it is possible to implement an ontology in Spanish, considering the recognition

DOI: 10.4018/978-1-7998-3479-3.ch059

of lexical-semantic relations, specifically hyponymy-hyperonymy and meronymy, based on the proposal of Arp, Smith & Spear (2015).

The organization of this article is as follows: section 1 shows a general background behind the notion of concept mining; the section 2 describes how is performed the identification of DCs, in order to detect and extract terms that function as hyponyms, hypernyms and meronyms. The section 3 exposes the results of these extractions, delineating a possible ontology that organizes such lexical-semantic information. To conclude, the section 4 offers a summary along with a brief discussion respect to future applications of this model of mining concepts.

BACKGROUND

Due to the current increasing amount of biomedical literature available on the Web, there is an interest for developing lexical-semantics resources oriented to improve searching and classification of biomedical concepts expressed in large-collections of texts. According to Sainani (2008) biomedicine has been characterized as an area with constant textual production, not only because of the large number of experts working within it, but also because today’s technological progress allows it to discover new knowledge, which must necessarily be documented and diffused in an expeditious and precise manner. An example is **MedLine** (<https://medlineplus.gov/>), a bibliographic database, which has an approximate total of 27.3 million citations and references to articles from 4,500 medical journals published in the United States and in more than 70 countries (Ananiadou, Kell and Tsujii, 2006). For accessing to such a MedLine, it is necessary to use the query engine PubMed (www.ncbi.nlm.nih.gov/pubmed/). Both resources, MedLine and PubMed, have a relevant impact in tasks related to the mining of data and texts.

Other example of this interest is the application to artificial intelligence system like IBM Watson (www.ibm.com/watson/health) for solving automatic analysis of medical data. Such analysis considers the use of natural language processing (NLP) techniques for inferring relevant terms and named entities that refer diseases, in order to support clinical diagnostics (Hoyt *et al*, 2016; Kaggal *et al*, 2016; Boukenze, Mousannif & Haqiq, 2016).

Figure 1. Development of an ontology according to the extraction of textual patterns (Buitelaar, Cimini and Magnini, 2005)

In this regard, Zweigenbaum *et al* (2007) explain that text mining has been applied in biomedicine to identify terms, named entities and lexical-semantic relationships. Furthermore, according to Bichindaritz & Akkineni (2006), as well as Poesio & Almuhareb (2008), the integration of these objects allows the configuration of semantic attributes, which configure concepts. From this approach, the concepts can be recognized in a document, in such a way that one can think of an extraction method capable of identifying them in specific textual patterns. Linking text mining with the creation of ontologies, Buitelaar, Cimiano & Magnani (2005) propose an extraction method that, in a staggered way, identifies such patterns:

According to Figure 1, in the first step a term extraction in a corpus is conceived. The next step is to search for possible synonyms linked to the terms extracted, either from the query of dictionaries, or using lexical networks such as WordNet. After this task, the next is to build a taxonomy, establishing a link among concepts with terms, according to a lexical relationships between hypernyms, hyponyms, meronyms, holonyms, etc. Then, in a plane of semantic representation, it is possible to delimit non-hierarchical relationships, in order to conceive semantic frames (e. g.: Baker, Fillmore & Lowe, 1998; Baker, Fillmore & Cronin, 2003), capable to shape a richer conceptual scheme. Finally, the last step represents a logical deduction for sketching the axioms that build an ontology, taking into account the conceptual relationships previously inferred (that is, the union among the lexical hierarchy whit the semantic frames).

DEFINITIONAL CONTEXT: A BRIEF DESCRIPTION

Following the experiments conducted by Navigli & Velardi (2004), as well as Velardi, Faralli & Navigli (2013), concept mining takes advantage using linguistic criteria to design algorithms capable to identify lexical and syntactic patterns associated to definitions. These authors have coincidences with the method proposed by Buitelaar, Cimiano and Magnini (2005) when designing **OntoLearn**, a system focused on the construction of ontologies based on the mining of terms and definitions. This system, it should be noted, is directed towards the processing of texts in English.

In parallel, Sierra, Alarcón & Aguilar (2006), Sierra *et al* (2008), as well as Sierra (2009) have been delineating a method of extracting concepts for Spanish through the identification of Definitional Contexts (henceforth, DCs). *Grosso modo*, a DC is text structure that introduces a term linked to a definition. There is a set of connectors that allows to establish this link, such as verbal phrases, pragmatic patterns and typographic marks, among others. See the following figure for more details:

Figure 2. Constitutive units of a DC structure

The Figure 2 shows the configuration of a DC around its basic components (term, verbal phrase and definition), as well as optional units (pragmatic patterns and typographic markers). The combination of these elements configure the linguistic structure of a DC within a text, in such a way that its detection helps to extract both terms and definitions directly.

A relevant subject that emerges in the light of the experiments carried out in the extraction of DCs, is to observe that the definitions assume specific features to express the concept associated with a term, depending on the type of verb that appears in the verbal predication. These features have to do with the formulation of the two basic components of the analytical definition conceived by Aristotle: *Genus Term* and *Differentia*. Taking into account the Aristotle's proposal, Sierra *et al* (2008) propose a typology, which distinguishes three derivable definitions from the analytical model, depending on the fact that the *Genus Term* or the *Differentia* are made explicit or not. It is possible to schematize such typology in the following way:

Figure 3. Typology of definitions according to the Aristotelian model (Sierra *et al*, 2008)

This typology can be better schematized in the following way:

- **Analytical or Aristotelian Definition:** will occur when the *Genus Term* and the *Differentia* appear explicitly within a definition.
- **Synonymical Definition:** will occur when a definition is made explicit the *Genus Term*, establishing a conceptual equivalence with the term that is defined.
- **Functional definition:** it will be given when the *Differentia* is made explicit, offering a definition of a term from its use or application in a given situation.
- **Extensional definition:** will occur when the *Differentia* is made explicit, which presents a definition that lists the components that make up an object represented by the term to be defined. This list of components will follow an order based on relationships that go from one whole to the parties, or from the parties to the whole.

These 4 types, in addition to expressing conceptual information different from one another, also provide the possibility of establishing a conceptual hierarchy that can be reinforced from the corroboration of existing lexical relationships, specifically: hyponymy/hypernym, meronymy and synonymy.

Analyzing now the relationship between verbal phrases and definitions, since Aristotle it has been considered as a logical operator, and it received the name of *predication* (Bäck, 2000). In fact, the idea

that the predication is linked to definitions has recently been reevaluated from a computational point of view (Guarino 1995, Cocchiarella 2003, Smith, 2004).

In concordance with this revaluation, Sierra *et al* (2008) and Aguilar & Sierra (2009) consider the predication as syntactic structure, which can be represented in a formal way using the predication theory (or PT). This theory is a model derived from Government & Binding Grammar formulated by Chomsky (1981). PT states that all predications indicate a semantic relationship between an entity and a particular property or characteristic feature (Rothstein, 1983; Bowers 1993, 2001; den Dikken, 2006). Syntactically, a predication configures a specific kind of phrase structure, just called *predicative phrase* (PrP), which is mapped by a functional head identified as the core of the predication. A graphical tree representation of a PrP is:

Figure 4. Tree representation for PrP, according to Bowers (1993)

Figure 4 shows the basic configuration of a PrP. According to Bowers (1993, 2001) the head assumes the features [+/-predication] to the functional head. Such head maps two subjects, a primary subject in the position of Specifier of PrP (represented by a Noun Phrase or NP); and a secondary subject, in the position of Specifier of Verbal Phrase or VP (often a NP). Finally, both subjects, the VP and the PrP are linked to one or more complements, which assume many phrasal representations such as NP, IP (Inflection Phrase), CP (Complement Phrase), and so on.

Bowers observes that the VP maps a symmetrical phrase structure to PrP. Therefore, it is possible to consider the subject of a VP as an object associated to the head of a PrP. This association is valid according to the rule of predicate linking. Thus, Bowers conceives two kinds of PrPs:

- a) If the predicate is linked to the subject mapped by the PrP, then it is a primary predication.
- b) In contrast, if the predicate is associated with the subject mapped by the VP, then it is a secondary predication.

We illustrate this distinction in the following examples:

- (i) [A **computer** [_{PrP}] [_{VP}] [_{IP}]].

- (ii) [Turing [defines a **computer** [as a kind of electronic device that processes a set of data_{PrP}] _{VP}] _{IP}]].

In (i), we observe a canonical case of primary predication, where the verb *is* inserts the predicate *a kind of electronic machine...*, linking it to the NP *a computer*. For the term extraction, the noun *computer* is equivalent to a term, while the predicate formulates the definition related to the term.

With regarding to (ii), the verb *defines* maps a PrP composed by three elements: a subject represented by the NP *Turing*, an object expressed by the NP *a computer*, and the predicate *as a kind of electronic device...* This predicate introduces a set of attributes that characterizes *a computer*, following the rule of association *Y is a predicate of X*. Both the predicate and the object configure a predicate linked to the subject through the verb *defines*, generating two symmetrical predicate structures: the first predication covers the subject *Turing*, the main verb, the object and the PrP; in contrast, the second predication covers the object *a computer* with the PrP whose head is the preposition *as*, according with the explanation offered by Bowers (1993, 2001).

From a terminological point of view, it can be considered that the subject of primary predication, as well as the object of secondary predication, represents a **term**. In contrast, the predicate introduced by the PrP represents the definition associated with the term.

FIRST TASK: TERM EXTRACTION

Once the grammatical structure of a DC has been analyzed, the next step has been to perform a term extraction task. For accomplishing this, it was designed a system with a hybrid approach —combining linguistic and stochastic criteria—, which uses a large reference corpus that facilitates the identification of candidates to relevant terms. For determining this assessment, a criterion of relative frequency ratios was used (Manning & Schütze, 2000).

The use of a set of reference texts is an effective method to give a relevant value to the vocabulary recognizable in a domain corpus, considering that the distribution of true and false terms varies between general documents compared to one of specialized texts (Kit & Liu, 2008). Thus, with this measure, a significant portion of the specialized vocabulary will have a high weight, and, consequently, the term candidate segments —specifically, NPs— will be more easily identified in a domain corpus.

The notion of *termhood*, proposed by Kageura & Umino (1996), allows determine the degree of specialization that a term candidate has. Therefore, a contrast is established with those functional words (articles, prepositions, pronouns, etc.), nouns and noun phrases whose meaning does not have any specialization use. Likewise —given its relationship with the notion of *termhood*— the *C-Value/NC-Value* algorithm has been implemented, developed by Frantzi, Ananiadou & Mima (2000). This algorithm works in two phases:

- a) A linguistic, which encompasses three processes: the use of morphosyntactic labeling, the application of nominal sentence formation rules that code potential terms, as well as the use of an unemployment list, which groups together the greatest number of words they do not have a terminological value, in such a way that they are outside the search process.
- b) A statistic, which establishes a measure of *termhood* considering the combination of the following factors: (i) the total frequency of occurrences of a term candidate within a corpus (be it a noun or a nominal phrase); (ii) the total frequency of occurrences of such candidate within a more extensive

string of words; (iii) the total number of extended chains that contain a term candidate; and (iv) the length of words of such chains.

Based on the performance of these phases, the method proposed here allows to set a measure of *termhood* to recognize good candidates. Such a measure is calculated considering formula:

$$\text{Termhood}(a) = f(a) \quad (1)$$

where a represents a string of candidate words at term, and $f(a)$ is its occurrence frequency within a corpus.

In order to better determine this measure, this algorithm also takes into account the neighboring words that appear around a possible term candidate. In short, it is established a contrast among the value of a word can have as a term given its frequency of appearance (*C-Value*), with the degree of specialization that said word has, taking into account its relationship with other neighbors within a text.

This algorithm has been adapted to Spanish by Barrón *et al* (2009), considering some modifications, namely: (i) the delimitation of a set of rules and syntactic patterns that operate as filters for the selection of nouns and nominal phrases that be candidates for terms; (ii) the possibility of selecting a stop list according to the user's criteria; and (iii) the lemmatization of the words contained in the corpus of analysis.

Although the experiment proposed by Barrón and others represents an advance, the results that reach in precision and coverage do not give a relevant balance, in specific his level of precision is of only 0.3, while his coverage reaches in one of its maximum values a 0.8. Given these results, the extracted candidates are not entirely reliable, therefore, is required a revision by an expert.

One of the factors that affects this low performance in the values of precision and recall is the use of a stop list prepared subjectively. In contrast to this criterion, in the experiment reported here was used a stop list extracted from a biomedicine corpus. Such stop list helped to filter good candidates for terms in a phase of selective elimination, p. e: the NP *distant lymph node*, after passing through this phase, is reduced as a *lymph node*, which leads to its consideration as an authentic term candidate. Emphasizing the role of adjectives as terminological units, Acosta & Aguilar (2015), as well as Acosta, Aguilar & Infante (2015), have analyzed their function to describe the attributes associated with a name, giving rise to a categorization of the referent expressed by said name within a specific conceptual domain.

Relational Adjectives Used for Extracting Terms

For this experiment is relevant to have in mind the syntactic and semantic role that relational adjectives play in the construction of biomedical terms. These adjectives, according to Demonte (1999), indicate features that ascribe to the noun within a specific class. Such features can be recognized in NPs such as *muscular inflammation*, *venereal disease* or *psychological disorder*, which follow the sequence: noun + relational adjective.

Taking into account the above, the method that was implemented here considers the use of two annotated corpus with Part-of-Speech (POS) tags, using the **FreeLing** system (Carreras *et al*, 2004). Once such annotation was made, the tags were standardized, in order to regulate the use of the preposition in cases of contraction (in Spanish: *del*), replacing it with the label *PDEL*. Similarly, in most cases, some tags were reduced to two characters, excepting the cases of the verb *estar* (English: *to be*), whose tag is VAE.

After the annotation, a **chunker** was developed to identify NPs that have a more adjective, according to the pattern: <NC> <AQ> *. Now, to eliminate those adjectives that are not relational (specifically, qualifiers), two patterns were implemented that allowed filtering of these:

<RG><AQ>

<VAE><AQ>

where RG, AQ and VAE (according to FreeLing), correspond respectively to adverbs, adjectives and the verb *to be*.

The next step was to apply the relative frequency ratio approach (Manning & Schütze, 2000) between two corpus—one of the biomedical domain and other of general language that serves as a reference—to assign relevance to the words common to both. For this, the formula used was:

$$weight(w_i) = \log_2 \left(1 + \frac{x_{dom}/N_{dom}}{x_{ref}/N_{ref}} \right) \quad (2)$$

where X_{dom} , N_{dom} corresponds to frequency of occurrence of w_i in domain and size of the vocabulary of names and adjectives of the domain, respectively. Similarly, X_{ref} , N_{ref} correspond to the frequency of occurrence of the word w_i and size of the vocabulary of the reference corpus. The unit added to the quotient of said formula is intended to avoid negative values.

On the other hand, the calculation of the relevance of the words that only occur in the domain with frequency of at least 2 was made considering only the logarithm of its frequency:

$$weight(w_i) = \log_2(f_{w_i}) \quad (3)$$

Finally, the words that occurred only in the domain corpus and only once, given that the reference corpus is large (5 million words), the fact that they do not appear in the reference corpus gives scope for considering that the probability of being domain words was high, so the decision to assign them a score of 1:

$$weight(w_i) = \log_2(1+f_{w_i}) \quad (4)$$

For its part, the calculation of *termhood* of each candidate was made through the sum of the relevance of each word present in such candidate: if a NP candidate (in Spanish: *fn*) has a length of n words, $w_1 w_2 \dots w_n$, then the relevance of the candidate is the sum of the weights of all the words w_i :

$$Rank(fn) = \sum_{i=1}^n weight(w_i) \quad (5)$$

The sum of all these values and formulas configures our method of extracting biomedical terms. We apply our method on a corpus with documents collected from **MedLineplus in Spanish** (www.nlm.nih.gov/medlineplus/spanish). The size of the corpus is 1.2 million words. On the other hand, a reference corpus of 5 million words was compiled, which contains news taken from the Mexican newspaper *La*

Jornada (www.jornada.unam.mx), specifically those of the year 2014. For the design of the chunker, it was used the NLTK library (www.nltk.org), developed in Python language (Bird, Klein & Loper, 2009).

Results of the Term Extraction

Without delimiting a specific threshold, and also without eliminating noise in the candidates, in a first phase it was obtained a precision of 33.6% and a recall of 90.4%. For the next phase the noise was removed, thus impacting positively on the results, since a precision of 46.5% and a coverage of 87.4 was achieved. Subsequently, when the C-Value / NC-Value algorithm was implemented to analyze the domain corpus, a precision of 27%, and a recall of 86% was reached.

This method allows establishing different thresholds of relevance (that is, *termhood*) to recover the best candidates. Thus, if a level greater than or equal to 1 is set, a precision of 53.4% and a recall of 85.6% is achieved. The thresholds that are greater than 10 achieve a precision above 70%, with a significant impact on a recall of 16%.

SECOND TASK: EXTRACTION OF HYPONYMS, HYPERNYMS AND MERONYMS

After performing the extraction of terms described in the previous section, the next task that we were going to solve was the identification of hyponyms, hypernyms and meronyms linked to those terms, taking into account the experiments reported by Acosta, Sierra & Aguilar (2015), as well as Acosta & Aguilar (2015, 2016). For carrying out such identification, we reuse our biomedical corpus in Spanish. Likewise, we made modifications to our chunker, in order to recognize NPs composed by nouns, relational adjectives and locative adverbs, considering this class of adverbs can help recognize parts of the human body, e. g. : *the gall bladder is in front of the liver*. The syntactic pattern that represents the noun phrases with a relational adjectives is:

<NC><AQ>

These NP patterns are useful for recognizing simple and complex terms, and also allow deducing possible hyponyms, which are located in a subordinate or specialized category. Previously, it is necessary to remove those NPs with qualifying adjectives, which do not provide candidates for relevant terms. For this, it is considered to elide the following sequences:

<RG><AQ>

<VAE><AQ>

<D.*|P.*|F.*|S.*><AQ><NC>

Using again the tags proposed by **FreeLing**, non-relevant phrase patterns composed of adverbs have been constituted (RG) preceding an adjective (AQ), or the verb *estar* (VAE) introducing an adjective. On the other hand, the <D tags. * | P. * | F. * | S. *> correspond to determinants, pronouns, punctuation marks and prepositions, which are also considered as elements of exception. All these restrictions are useful to reduce the noise that can present false positives at the time of extraction.

Regarding the identification of meronyms, we have considered patterns of nominal phrases that project the axial properties of a reference object (Acosta & Aguilar, 2015; 2016). Under such consideration, both those that include adverbs of place and the preposition of are good candidates, since they refer to specific entities located in a spatial framework represented by the human body. The regular expression to identify this information is:

<RG><PDEL><DA>?<NC><AQ>*

Calculating the Relevance of Identified Candidates

For determining how relevant the candidates we have identified in the analysis corpus are, the relative frequency relationship has been calculated using formula (2). On the other hand, the relevance of the words that only occur in the domain corpus is calculated considering the following formula:

$$weight(fn) = freq(fn) + \left(\sum_{i=1}^n weight(w_i) \right) \quad (6)$$

Where was determined the weight of NPs recognized in such corpus. The classification of candidates for term is done by adding the individual ranges of words present in the identified pattern. In this sense, what is expected is that the higher the frequency of the appearance of noun phrases, the greater their stability as a syntactic structure that projects a biomedical term. It is important to remember that before calibrating the ranges of candidate of NP, these have already been stripped of those non-relevant elements, which facilitates the calculation of their frequency of occurrence.

It should also be added to eliminate the non-relevant vocabulary of the domain corpus, the same criterion used in the term extraction was followed: a contrast was made with a reference corpus previously mentioned, based on news taken from the Mexican newspaper *La Jornada*.

RESULTS AND CONCLUSION

Once the search and collection of the patterns described previously has been carried out, the sets of candidates for hyponyms, hypernyms and meronyms obtained are evaluated. In the case of hyponym/hypernym relationships, the following results were obtained:

Table 1. Precision, recall and f-measure for the detection of hyponyms and hypernyms

Phase	Recall	Precision	F-Measure
Baseline	87%	17%	28%
Chunker	58%	62%	60%
Filter 1	57%	68%	61%
Filter 2, Frequency ≥ 5	42%	80%	55%
Filter 2, Frequency ≥ 6	40%	81%	54%
Filter 2, Frequency ≥ 10	35%	84%	49%
Filter 2, Frequency ≥ 20	27%	90%	42%

What is exposed in this table are the results of precision, recall and F-Measure. The baseline used here consists in extracting candidates to DCs, which introduce PrPs whose heads are verbs such as *to be*, *to characterize*, *to conceive*, *to define* and others similar, according to Sierra *et al* (2008). The proposed chunker managed to achieve a recall of 58% and a precision of 62%. Applying the first causal relationship filter, it is obtained a precision of 68% with a reduction in recall of 57%. Likewise, the application of thresholds of occurrence of hypernyms shows the best results in precision, but as the thresholds increase, the recall is markedly reduced.

In the case of meronym relationships, 5 evaluation phases have been established. In the first, which corresponds to the extraction of specific entities, achieved a precision of 73%. In the next, the precision decreased to 51%. In the remaining phases (3 to 5) they show no changes with respect to their precision. Given these results, the meronyms were extracted with the set obtained from phase 1, in such a way that the candidates from the remaining factions were not analyzed. It should also be added that a general recall of 65% was achieved.

One of the relevant results of this experiment was the level of precision in the recognition of domain terms: as can be seen in table 2, it was higher than 70%. Likewise, it can be observed that the extraction of specific entities tends to converge in phase 5:

Table 2. Levels of precision of candidates for specific entities in meronymy relationships.

Phase	Precision	Concrete Entities	Candidates	Terms
1	73%	308	423	74%
2	51%	566	1109	74%
3	46%	744	1632	72%
4	44%	806	1849	71%
5	43%	821	1891	71%

To conclude, it is clear that the mining concepts applied to extract relevant medical information is a complex task that requires many levels of refinements at syntactic and semantic levels, particularly:

- The recognition and filtering of syntactic patterns that show good candidates for terms and definitions, which can be reused when necessary.
- The analysis and inclusion of patterns that indicate other semantic relationships different from those that have been shown here, e. g: causal (*the Helicobacter Pylori is a bacterium that **causes** gastritis and peptic ulcer*), locative (*the pylorus **is situated in** the lower part of the stomach*), telic (*hepatocytes **produce** bile secretions*), and others. Taking these relationships into account will allow the development of a much more detailed model of ontology, thinking in the information obtained through mining previously proposed.
- The application of models such as Markov chains, support vector machines, neural networks and others that allow the implementation of automatic learning methods, in order to provide a relevant degree of independence to the extraction system, which allows it to improve the accuracy of their results, and thereby reduce the human evaluation process.

Therefore, applying the processes of recognition and extraction of DCs, we can obtain terms associated to definitions. Integrating all the lexical-semantic relationships recognized, it is possible to implement an

ontology that allows organizing concepts related to terms. These terms will be extracted from DCs, and the concepts will be derived from analytical definitions. In addition, it is necessary to search synonyms related to these terms. An example of such ontology can be seen in the following figure:

Figure 5. Example of a possible ontology based on medical terms (Aguilar, Sierra & Acosta, 2012)

The Figure 5, we can distinguish a set of sub-terms linked to the main term *ojo* (Eng. *Eye*). These sub-terms operate as nodes, and the possible lexical relations are branches connected with the main term. Thus, based on a lexical relation of Parth-Whole, we can infer that cornea is a constituent of *ojo*. In contrast, the term *enfermedad* (Eng. *Disease*) is an attribute. Finally, the *glaucoma* is a *type of disease* that affects the eyes. This last phase about the generation of a graph that associates the existing relationship between terms is a work still in process.

FUTURE RESEARCH DIRECTIONS

We believe that the results presented here are an empirical support that justifies the implementation of methods for mining concepts on large corpora based on NLP techniques. Although in this case we focus mainly on the identification of terms as well as segments immersed in lexical relations (specifically: hyponyms, hypernyms and meronyms), it should be noted that these lexical units are useful for generating a taxonomy, whose semantic information of the actual use of such units in specialized texts.

Thus, a next step would be to extract the entire DC identified in a text, and infer other semantic relationships contained in it, e. g.: causal relationships such as those of effect-cause (*H. Pylori is a gram-negative bacterium {causes/incites/generates} gastritis*), source-goal (*the gastrointestinal tract starts in the oral cavity and ends in the anus*), containment (*proteins are {formed by/integrated by/contain} amino acids*), and so on. This idea is aligned to the methodology proposed by Buitelaar, Cimiano & Magnini

(2005). Thus, it is possible to employ our processes for recognizing and extracting analytical definitions in DCs in order to build an ontology according the method proposed by Buitelaar, Cimiano, and Magnani.

KEY TERMS AND DEFINITIONS

Concept: A mental construction which contains information about a specific entity based on our knowledge and our experience.

Concept Mining: A kind of task derived from the knowledge discovery, focused to recognize patterns in large collections of unstructured data (that is, linguistic corpora), which contain relevant information associated to concepts. For solving such task, it is employed different methods based on NLP (e.g., tokenization, lemmatization, POS tagging, syntactic and semantic analysis, and others).

Definitional Context: A discursive fragment constituted by a term, a definition, and linguistic or metalinguistic connector as predicative phrases, typographical markers, or pragmatic patterns.

Hyponymy-Hypernymy: A kind of hierarchical lexical relation where is established a conceptual subordination between the meaning of two or more words (e.g., **a robin** [hyponym] *is a kind of bird* [hypernym]).

Lexical Relationship: A conceptual link established between words grouped around a lexicon.

Meronymy: A semantic relation specific to linguistics, distinct from the similar metonymy. A meronym denotes a constituent part of, or a member of something (e.g., **wheels** *are part of an automobile*; **a policeman** *is a part of a police department*, etc.).

Ontology: A system of representation that shows the formal naming and definitions of the categories associated to entities. It describes the properties and relations between the concepts refer by such entities, situated in a specific or general knowledge domain.

Term: A word or compound words that designates a specific entity, event or relation into the framework of a scientific or technical knowledge domain.

Text Mining: A process of deriving high-quality information from text. This kind of task involves information retrieval, lexical analysis to study word frequency distributions, pattern recognition, tagging/annotation, information extraction, data mining techniques including link and association analysis, visualization, and predictive analytics. The overarching goal is, essentially, to turn text into data for analysis, via application of natural language processing (NLP) and analytical methods.

INTRODUCTION

Information is increasingly global, which brings with it the growth in a non-English speaking public and, as such, a demand for tools that allow users to access this information. Faced with this scenario, the development of new tools and technologies is a key element. This is the case of Machine Translation (MT), one of the most popular and used tools to overcome linguistic barriers. As a result, linguistic companies are increasingly offering services related to MT as, in many cases, it is impossible to meet the demand for translations only with human translators. In addition, MT systems can be integrated with other tools and resources such as Translation Memories—databases which store already translated text for future use—or multilingual terminology databases—also known as glossaries—in order to improve the efficacy of the translation process.

In this chapter an overview of MT development since its early beginnings in the late 1950s until the present day is proposed. The evolution of MT techniques will be reviewed starting from the traditional approaches—Statistical and Rule-Based MT—and finishing with the latest trends, which include hybrid MT systems, Adaptive MT and Neural MT.

BACKGROUND

Brief History of Machine Translation

The origins of Machine Translation date back to the 17th century, as during this time an interest for creating an universal language based on logic principles and iconic symbols and for developing mechanical dictionaries arises (Hutchins, 2007). During the following centuries, there were some proposals to create international artificial languages, among which stood out Esperanto (Hutchins, 1995; Hernández-Mercedes, 2002). However, there were no real attempts for automating translation until 1933, when two patents were issued for machines functioning as multilingual mechanical dictionaries, designed to find

DOI: 10.4018/978-1-7998-3479-3.ch060

the equivalent of a word in another language. One patent was issued in France, to Georges Artsouni, and the other one in Russia, to Petr Trojanskij. During the 1940s Andrew Booth and Warren Weaver developed the first ideas which involved computers for translating natural languages and worked with Richard H. Richens on morphological analysis for a mechanical dictionary (Hutchins, 1995).

In 1951 Yehoshua Bar-Hillel, from the Massachusetts Institute of Technology (MIT), outlined some of the basic approaches to MT in a state-of-the-art-report and one year later the first MT conference was held at MIT. The conference evidenced that good quality MT was not possible, as long-term research was needed. Therefore, at that stage, human intervention was required before (pre-editing) or after (post-editing) the process. In addition, during the conference it was also highlighted that a public demonstration was necessary in order to attract funding (Hutchins, 2007; Hernández-Mercedes, 2002). Two years later, in 1954, the first public demonstration of an MT system was carried out as a result of a joint project between IBM and Georgetown University. Despite not having a remarkable scientific value, this demonstration was the starting point for large-scale funded MT research in the USA and for the developing of MT projects around the world, especially in the USSR (Hutchins, 1995).

During the following ten years, there were two main approaches regarding MT research. On the one hand, empirical approaches focused on statistical methods in order to discover grammatical and lexical regularities. On the other hand, theoretical approaches were based on linguistic research, which led to the beginnings of computational linguistics (Hutchins, 2007).

Even though during this decade research on MT field seemed promising, the linguistic and semantic problems became more and more noticeable. Therefore, the National Science Foundation was asked by government sponsors in the USA to assess future prospects of MT. For this purpose, the Automatic Language Processing Advisory Committee (ALPAC) was formed in 1964. The ALPAC report in 1966 pointed out that MT was slower, less accurate and twice as expensive as human translation. Consequently, the ALPAC report meant a significant reduction in MT research and development (Dorr, Jordan, & Benoit, 1999). Despite the impact of the ALPAC report, some research groups at the University of Texas and at Wayne State University continued researching on MT in the USA, which were focused on translating scientific and technical materials from Russian into English (Hutchins, 2007). However, between 1967 and 1977, MT research was carried out mainly in Canada and Europe. There was a high demand for English-French translations in Canada due to its bicultural policy. For its part, in the European Community, it was necessary to translate scientific, technical, administrative and legal documentation into all the languages of the European Community. During the decade of 1970, at Montreal, researches of the TAUM project (Traduction Automatique de l'Université de Montréal) designed Méteo, a system for translating weather forecast (Dorr et al., 1999). During the same years, the European Community purchased an MT system called Systran—developed by Peter Tomas—and, at the end of the 1970s, decided to establish a research project called EUROTRA, whose aim was to create an MT system for all the official languages of the European Community (Alcina Caudet, 2011).

In the 1980s, Systran continued to evolve and include more languages while new systems such as LOGOS or METAL entered the market. Special-purpose MT systems—designed for particular environments—were also developed. That was the case of SPANAM and ENGSPAN, two systems developed by the Pan American Health Organization (Hutchins, 2007).

During the 1980s, research groups continued working on MT. For instance, the GETA (Groupe d'Études pour la Traduction Automatique) group developed the Ariane system, which influenced MT projects around the world. In 1986, the research prototype of the Mu system, which was conceived at the University of Kyoto, became an operational system used by the Japanese Information Center for Science and Technology. This project influenced Japanese computer companies, which started to invest

and develop computer-aided translation software (Hutchins, 2007). The increase of the availability of personal computers and text processors resulted in cheaper MT systems, which were exploited by companies such as ALPS, Globalink, NEC and Sanyo, among others (Hernández-Mercedes, 2002). During this years, research on MT continued and projects were developed in Europe, Korea, Taiwan, China, North America and the Soviet Union (Hutchins, 1995).

In the 1990s, the use of MT systems by commercial agencies, government services and multinational companies was consolidated and Systran, Logos, METAL and ATLAS systems dominated the market. In addition, new fields of research, such as software and website localization, emerged and, given the need of immediate translations, MT—along with other resources like Translation Memories—become a popular tool in this areas. Numerous systems for personal computers appeared and started to be commercialized, normally in three basic versions: for large corporations ('enterprise' systems), for independent translators ('professional' systems) and for non-translators ('home use') (Hutchins, 2007). In addition, from 1995 on, internet-based translation services appeared and, even though the quality was generally poor, they met the demand for immediate translation for information purposes (Hutchins, 2007).

From the 2000s on, MT has been a very prolific research field (España-Bonet & Costa-jussà, 2016). As a result, new approaches continuously emerge and different technologies and techniques are being quickly developed in order to improve MT systems as much as possible. In the following section, MT strategies and techniques will be revised starting from the first traditional approaches and finishing with the newest tendencies in this field.

MACHINE TRANSLATION APPROACHES

Traditionally, two main basic approaches were distinguished concerning MT: the rule-based approach and the corpus-based approach. However, in the recent past years MT research has explored new techniques and architectures, resulting in new approaches such as Hybrid MT, Adaptive MT and Neural MT.

Rule-Based Machine Translation

Rule-Based Machine Translation (RBMT) systems use monolingual and bilingual dictionaries and grammar rules as the basis to generate translations (Hutchins & Somers, 1992; Okpor, 2014). Three basic MT strategies can be identified with regard to RBMT systems: direct, interlingual and transfer. These approaches are traditionally represented using the Vauquois triangle (Figure 1).

Figure 1. Vauquois triangle (adapted from Vauquois, 1968)

Direct Approach

The direct approach was used by the first generation of MT systems (Hutchins & Somers, 1992). There are not intermediate stages in the translation process, that is to say, the source language input is replaced word by word in the target language. Some local reordering rules are followed in order to achieve a more precise target language output (Hutchins & Somers, 1992; Prószéky, 2005).

The first MT system—called IBM701 and developed jointly by Georgetown University and IBM—was based on the direct approach (Peng, 2013).

Interlingual Approach

The interlingual approach analyses the source text using an intermediate representation, which includes all the necessary information for generating the target text. This neutral and abstract representation acts as a projection from the source text which, at the same time, is the basis for the generation of the target text (Hutchins & Somers, 1992; Okpor, 2014).

The UNITRAN system, developed at the Artificial Intelligence Laboratory of the MIT (Dorr, 1987), and the KANT system, developed at Carnegie Mellon University (Nyberg, Kamprath, & Mitamura, 1998) are examples of MT systems using interlingual architecture.

Transfer Approach

The transfer approach transforms the source language into an intermediate representation and an equivalent representation is generated for the target languages using dictionaries and grammars (Hutchins & Somers, 1992; Okpor, 2014; Tripathi & Sarkhel, 2010). The difference with interlingual MT is that the transfer approach depends on the language pair involved (Okpor, 2014). The translations are carried out in three stages: analysis, transfer and generation. In the first stage the source text is analyzed based on linguistic information in order to produce its representation; the next stage aims to transfer the source language representation into the semantic/syntactic structure of the target language. In the final stage a target language morphological analyzer is used to generate the final output (Okpor, 2014; Tripathi & Sarkhel, 2010).

The MANTRA system, developed by the Applied Artificial Intelligence Group (AAI) of C-DAC (Center for Development of Advanced Computing) in Pune (India), translates documents from a variety of domains from English to Hindi using a transfer-based approach (Gehlot et al., 2015). The Dan2eng system, for Danish-English, also uses a transfer-based approach to translate unrestricted text from a wide range of genres (Bick, 2007).

Corpus-Based Machine Translation

From 1989, new methods and strategies—known as corpus-based methods—emerged and gained popularity, replacing the dominant RBMT systems (Hutchins, 2007). Corpus-Based Machine Translation (CBMT) systems use bilingual parallel corpora, consisting in texts paired with their translations, which are used to obtain translation knowledge with the aim to achieve the highest possible level of accuracy (Ballabh & Chandra Jaiswal, 2015; Okpor, 2014). We can distinguish between two main approaches concerning CBMT: Statistical Machine Translation (SMT) and Example-Based Machine Translation (EBMT), although it is important to mention that Somers (1998) argues that SMT is example-based

approach and Hutchins (2007) states that both approaches converge in many respects and, consequently, isolating the distinctive features of both approaches is a very complex task.

Statistical Machine Translation

SMT is based on machine learning, a learning algorithm is applied to large volume of corpora—which include many samples of human translations—so that the system is able to learn automatically how to translate without human intervention (Dajun & Yun, 2015; Lopez, 2008). Therefore, SMT is based on probabilistic models that take into account both the relations in the source and the target language to generate the output (España-Bonet & Costa-jussà, 2016). Depending on the minimal unit for translation, three different approaches can be distinguished: word-based, phrase based or syntax-based (España-Bonet & Costa-jussà, 2016; Tripathi & Sarkhel, 2010).

There are many examples of SMT systems. For instance, the open-source SMT Moses allows to train translation models for any language pair (Koehn et al., 2007). Within the commercial MT systems, the company SDL International acquired Language Weaver, an SMT system developed at the University of Southern California's Information Sciences Institute, which can be integrated with SDL computer-assisted translation tools and it is available for 75 language pairs (Alcina Caudet, 2011; Benjamin, Gerber, Knight, & Marcu, 2003). The well-known companies Microsoft and Google used the statistical approach in their MT systems—Microsoft Translator and Google Translate. However, since 2016 both companies shifted towards artificial intelligence and both MT systems were updated to implement Neural Machine Translation (NMT) (Microsoft blog editor, 2018; Wu et al., 2016).

Example-Based Machine Translation

EBMT is based on translation by analogy. An EBMT system extracts from a corpus or database segments of texts written in the source language in order to generate a text in the target language with the same meaning (Hutchins, 2005; Okpor, 2014; Somers, 1999). EBMT entails matching new input—sequences of words—against the database so that suitable examples are extracted and recombined to generate the correct translation in the target language (Okpor, 2014; Somers, 1999).

As previously stated, it is difficult to clearly distinguish between SMT and EBMT systems and, as a consequence, EBMT systems and SMT normally share features of their paradigms. This is the case of Cunei, a hybrid EBMT and SMT system (Phillips, 2011) and CBU-EBMT, a complete end-to-end system available under the GNU General Public License (Brown, 2011).

Hybrid Machine Translation

Hybrid Machine Translation (HMT) combines system components of RBMT and SMT into new systems with the aim to join the advantages of two approaches (Hunsicker, Yu, & Federmann, 2012; Tambouratzis, 2014; Thurmair, 2009). In this sense, HMT systems try to overcome the problems caused by these two approaches separately in order to increase the quality and accuracy of translations (Gutiérrez-Artacho, Olvera-Lobo, & Rivera-Trigueros, 2018; Hunsicker et al., 2012; Tambouratzis, 2014).

Hybridization of MT can be carried out following several techniques but, in general terms, we can distinguish between hybridization led by an RBMT system or an SMT system (Costa-Jussà & Fonollosa, 2015; España-Bonet & Costa-jussà, 2016). On the one hand, SMT systems can be integrated with RBMT systems in order to improve syntax and grammar. This integration can be performed at a superficial

level—by using rules at pre/post-processing—or at a deeper level—integrating RMBT features into the core translation model of an SMT system (España-Bonet & Costa-jussà, 2016). On the other hand, RBMT systems can integrate data information to improve lexical selection and fluency (Costa-Jussà & Fonollosa, 2015; España-Bonet & Costa-jussà, 2016). Three classes that summarize the integration of both approaches can be distinguished: enriching the basic resources of RBMT with data obtained from corpora; including data-based modules in the RBMT process and using RBMT as a backbone, which consist of the combination of individual systems where the rule-based one dominates (España-Bonet & Costa-jussà, 2016).

In 2009, AppTek launched the first complete HMT system, called TranSphere, which provided a full integration of RBMT and SMT methodologies (Boretz, 2009). The same year, Systran released SYS-TRAN Enterprise Server 7, the first HMT server of the company combining the RBMT and the SMT approaches (Moran & Donlan, 2009). Nowadays, both companies have implemented the neural approach into their MT systems. In 2012, ProMT presented the ProMT DeepHybrid system, which was based on a RBTM engine which incorporates an statistical phrase-based post-editing component (Molchanov, 2012).

Adaptive Machine Translation

The idea behind Adaptive MT is that the system learns from user feedback in order to avoid repeating the same mistakes in future sentences (Farajian, Bertoldi, & Federico, 2014). Therefore, this paradigm is focused on the post-editing phase, as the systems incorporate the human feedback immediately via online updates (Denkowski, Lavie, Lacruz, & Dyer, 2014).

SDL released SDL Trados Studio 2017, which is designed to be used when no translation memory match is available. The MT engine is updated as users accept new suggestions—in a similar way as a translation memory will be updated—and MT mistakes do not need to be corrected every time, which reduces the post-editing effort. SDL claims that this technology shift means MT and translation memory technology start converging (Ferguson, 2016; Whale, 2017).

Neural Machine Translation

Neural Machine Translation (NMT) is a new approach that aims to train a large neural network that reads a sentence and generates a correct translation (Bahdanau, Cho, & Bengio, 2015). NMT is based on the encoder-decoder model. The encoder reads a source sentence and extracts a fixed-length representation and the decoder generates a correct translation from the previous encoded vector (Bahdanau et al., 2015; Cho et al., 2014). In addition, neural networks can be trained for specializing in specific domains (Wołk & Marasek, 2015).

As previously mentioned, some of the main MT companies have shifted towards NMT. Google launched in 2016 Google's Neural Machine Translation system (GNMT), whose network includes 8 encoders and 8 decoders layers (Wu et al., 2016). Recently, Google is working on hybrid models combining different NMT architectures to develop what they have called the RNMT+ model (Chen et al., 2018). On the other hand, Systran introduced Pure Neural Machine Translation (PNMT) in the same year, which is now available in Systran Enterprise Server and it also embedded in mobile applications (Crego et al., 2016; Systran, 2017). In addition, Systran share research results in OpenNMT, an open source initiative for neural machine translation and neural sequence modeling (Klein, Kim, Deng, Senellart, & Rush, 2017). Microsoft Translator adopted the NMT approach in 2016, which was also implemented by Skype Translator and the Microsoft Translator app for mobile devices (Microsoft Translator, 2016). In May

2018, Microsoft updated their MT system for allowing users to customize the NMT systems (Microsoft blog editor, 2018). Finally, other well-known companies such as Facebook and Amazon are also using NMT in their translation services (Lample, Ott, Conneau, Denoyer, & Ranzato, 2018; Lu et al., 2018).

Summary of MT systems

There are numerous MT systems available, either open-source systems or commercial systems. The European Association of Machine Translation (EAMT) offers a comprehensive directory of commercial MT software on its website (EAMT, 2010). In the previous sections some MT systems have been referred to illustrate the approaches described. Table 1 shows a brief summary of the different MT systems mentioned in the previous sections.

Table 1. MT systems summary

MT Approaches		MT systems	Available at:
RBMT	Direct approach	IBM701	Not available. See IBM press release (January 8, 1954) for more information.
	Interlingual approach	UNITRAN	Not available. See Dorr (1987) for more information.
		KANT	KANT project website
	Transfer approach	MANTRA	CDAC website
		Dan2eng	SDU website
CBMT	SMT	Moses	Moses website
		Language Weaver	SDL Language Weaver website
	EBMT	Cunei	Cunei website
		CBU-EBMT	Not available. See Brown (2011) for more information
HMT		TranSphere	TranSphere website
		ProMT	ProMT website
Adaptive MT		SDL Trados Studio 2017	SDL website
Neural MT		Google Translate	Google Translate online translator
		Systran	Systranet online translator
		Microsoft Translator	Microsoft Bing online translator

SOLUTIONS AND RECOMMENDATIONS

There is no doubt that many advances have been made concerning MT. New technologies and systems are rapidly emerging and evolving achieving significant milestones. However, MT has still its limitations. For instance, NMT is computationally expensive as its training configurations often takes a few weeks (Crego et al., 2016). In addition, NMT can make errors such as removing words, mistranslating proper names or rare terms or not taking into account the context of the translation (Wu et al., 2016). As a consequence, measuring the performance of MT system will be required to be able to progress in its research, development and improvement. To this end, Shaw and Gros (2007) list in their work a number of methods—including human and automatic criteria—that can be used to assess the efficacy of MT. In addition, as MT, in general terms, does not reach the quality of human translations post-editing has

become essential part of the translation process if we wish to obtain translations of the highest possible quality (Gutiérrez-Artacho et al., 2018). In this sense, developing post-editing guidelines will help to increase the efficacy of this process. Several authors offers post-editing guidelines (Hu & Cadwell, 2016; Mesa-Lao, 2013; O' Brien, 2009; TAUS, 2010; Wagner, 1985), although further research, specifically for MT in specific domains is still needed.

FUTURE RESEARCH DIRECTIONS

It is clear that MT is an evolving field and new approaches will rapidly emerge. Nowadays, the main research areas are focused on NMT. However, there are new works that aims to integrate NMT technology into interactive machine translation framework to foster human-computer collaboration (Peris et al., 2017). In fact, there is already one available system—Lilt—that uses the artificial intelligence from NMT and the real-time feedback of Adaptive MT to increase translator's productivity (Lilt, 2017). It can be expected that in the near future ever more companies will research on the joint implementation of this two recent approaches giving birth to a new generation of hybrid architectures. To finish with, in relation to MT evaluation, nowadays, the most used metrics are targeted to SMT systems (Way, 2018). Therefore, as new approaches arise, evaluation metrics adapted to the new features of MT systems are expected to be developed as well. Moreover, new research areas are focused on integrating MT with web localization and the emerging field of transcreation—translating and adapting a message from a source language to evoke the same emotional response in the target language— in order to assess the impact of MT with regards to the post-editing process.

CONCLUSION

MT is clearly an active and growing field of research, long gone are the days of the ALPAC report when there were no feasible prospects for MT. Global access to information and the increase of the non-English speaking audience imply the demand for tools allowing users to secure information from a wide range of resources. MT has proven its potential for overcoming linguistic barriers for professional translators, companies, institutions and private users. As a consequence, the demand for MT is generalized and growing, especially in the multilingual context of the Internet.

MT does not limit itself to the linguistic field, as it could turn really useful in fields such as Medicine or Information Retrieval, among others. For instance, MT results especially convenient when there is a high demand for translating large amounts of texts and human translators alone could not satisfy it due to time or cost constraints. In addition, MT systems, can be integrated together with other resources such as Translation Memories, glossaries or terminology databases for contributing to carry out the translation process in a quicker and more efficient manner. In the future, we can expect an increasing demand for MT services, which will lead to new advances and technologies. However, the quality of machine translations is still deficient, compared to professional human translations. As a consequence, new evaluation metrics and methodologies should be developed to assess MT quality, taking into account human and automatic criteria. As nowadays post-editing is still required to achieve high quality translations, there should also be a focus of research on this field—including competences, guidelines and the role of post-editors within the translation process.

KEY TERMS AND DEFINITIONS

Adaptive Machine Translation: Machine translation systems whose architecture uses user feedback in order learn and to avoid repeating mistakes.

Corpus-Based Machine Translation: Machine translation systems whose architecture is based on the analysis of bilingual or multilingual corpora.

Hybrid Machine Translation: Machine translation systems whose architecture is based on the combination of the rule-based and the corpus-based approaches with the aim to combine the advantages of both approaches.

Machine Translation: The automatic process carried out by a software for translating text from one language to another.

Neural Machine Translation: Machine translation systems whose architecture is based on artificial neural networks.

Post-Editing: The revision process for a text that has been previously translated by an MT system.

Rule-Based Machine Translation: Machine translation systems whose architecture is based on linguistic information retrieved from dictionaries and grammars.

Translation Memory: A linguistic database that stores previously translated text so it can be reused for generating new translations.

Migrating Software Towards Mobile Technologies

INTRODUCTION

Today, the use of technology is central to the business world. Organizations need to redesign their processes and models so as not to be left out of the market in the near future. The adoption of new digital technologies offers a competitive advantage and performs as a market differentiator. In particular, new paradigms such as Pervasive Computing, Cloud Computing and the Internet of Things (IoT) are impacting the business world. Smartphones are at the core of these paradigms, letting us locate and easily interact with the world around us. With the Smartphone through Wi-Fi and the 5G, we will handle all kinds of objects connected to the network. Just as smartphones have already displaced the camera, the GPS, the music player, and the wallet, they will be on-ramp for a new IoT revolution. In this scenario, humans and things act synergistically as a whole and smartphones will continue to play a crucial role due to they are the main interface connecting people to the Internet (Stancovik, 2014) (Islam and Want, 2015). Smartphones are being transformed into a service center for different platforms in science, medicine, and education. Hossain et al. (2019) analyze the effects of variety-seeking intention by mobile phone usage on university students' academic performance.

In this context, most challenges for the competitive software industry are related to the problems caused by the proliferation of mobile platforms. New applications must support them as possible to remain profitable. Software applications can take full advantage of platforms only when they are built using native codebase. To address this problem a possible solution is to have different teams of developers who are fluent in a specific programming language to port an application to a specific platform. Instead of this traditional approach, organizations can use multiplatform or multi-paradigm cross-compiler based languages. The term “multiplatform” is used to refer source-source compilation, that is to say, the source code of these languages can be compiled into the source code of another programming language. Haxe is a good example of multiplatform languages. It allows using the same code to deploy an application on multiple platforms such as iOS, BlackBerry or Android. Specifically, it is an open-source high-level multiplatform programming language and compiler that can produce applications and source code for many different platforms from a single code-base (Haxe, 2019).

Frequently, the development of software component and applications aligned to mobile technologies requires adapting existing non-mobile software to different mobile platforms. For instance, there exist valuable software components and libraries implemented in C/C++ or Java that need to be adapted for mobile developments. There is the need to define systematic, reusable migration processes with a high degree of automation that reduce risks, time and costs of the cross-platform development. Novel technical frameworks for information integration, tool interoperability, and reuse can help to achieve these goals. Specifically, Model- Driven Engineering (MDE) is a software engineering discipline which emphasizes

DOI: 10.4018/978-1-7998-3479-3.ch061

the use of models and model transformations to raise the abstraction level and the degree of automation in software development (Brambilla et al., 2017). Productivity and some aspects of software quality such as maintainability or interoperability are goals of MDE.

Model Driven Developments (MDD) refer to forward engineering processes that use models as primary development artifacts. A specific realization of MDD is the Model-Driven Architecture (MDA) proposed by the Object Management Group (OMG) (MDA, 2019). Models, metamodels and model transformations play a major role in MDA. The MDA processes can be seen through a sequence of model transformations at different abstraction levels. A transformation is a process of converting a source model that conforms to a source metamodel in a target model that conforms to a target metamodel. The essence of MDA is Meta Object Facility (MOF), an OMG standard for defining metamodels that provides the ability to design and integrate semantically different artifacts in a unified way (MOF, 2016).

The OMG Architecture-Driven Modernization Task Force (ADMTF) is developing a set of specifications and promoting industry consensus on modernization. ADM is defined as “*the process of understand and evolve existing software assets for the purpose of software improvement, modifications, interoperability, refactoring, restructuring, reuse, porting, migration, translation, integration, service-oriented architecture deployment*” (ADM, 2019).

MDE progresses in the direction of achieving to develop software as reliable as any other engineering product, however, its impact on the software industrialization is limited. The main reasons are due, on the one hand, to a lack of repositories that contain reliable metamodels of the programming languages, and transformations between the different metamodels. It is worth considering that, MDE developers, instead of needing CASE tools to support the development on specific platforms, need to reuse metamodels and transformations. The incipient degree of progress in the specification of them requires that the developer, in general, must build them from scratch. This implies additional costs and time involved in these activities that must be compared with the total benefit. In addition, it is important to note that the construction of a metamodel should be considered critical development since the instances of a metamodel (models) must be reliable but currently, it is not focused in this way.

On the other hand, Model-driven approaches were broadcast emphasizing on processes viewed as a sequence of transformations between metamodels defined through the official standards. However, it is convenient to have a more flexible vision of MDE that allows integrating software developed from other frameworks or tools that have been tested through its use for several years and software developers prefer to continue using them. For example, software developers prefer to use multiplatform languages over model-driven developments that require defining metamodels and transformations for all multiple mobile platforms. Integrating multiplatform languages to MDE developments for the modernization of software would not imply defining metamodels and transformations for all the platforms it supports, but only for the multiplatform language.

Metamodeling is crucial in Model-Driven processes. It is important to formalize and reason about MOF metamodels and we propose to exploit the strong background achieved by the community of formal methods. Formal methods provide systematic and rigorous techniques to reduce ambiguities and inconsistencies in software development. Within the next few decades, tools based on verification will be as useful and widespread for software development as they are today in critical systems (Beckert and Hahnle, 2014). Behind the specifications and formal methods exists a community that has developed theories, languages, methods, and tools, but the software industry does not take advantage of them, in particular, to effectively address the software crisis. There is already a substantial body of research, tools and case studies demonstrating that it is possible to develop software as reliable as any other engineering product. To enhance the software industry, artifact analysis tools that support novel combinations

of code analysis techniques, model checking, testing and theorems provers are emerging (Beckert & Hahnle, 2014).

In this chapter, we describe a lightweight MDE approach based on the ADM standards. In this context, a lightweight process is the one that leaves open the possibility to fall back to the traditional methodology without model-driven standards. It is based on the integration of cross-platform frameworks, and formal methods with ADM. First, an infrastructure for the definition of reliable metamodels that integrates semi-formal and formal specifications based on algebraic specifications of metamodels is analyzed. Next, an integration of ADM standards with cross-platform development for the migration of desktop software to mobile platforms through the multiplatform language Haxe is described. A repertory of new metamodels and transformation necessary to adapt object-oriented software to different mobile platform through Haxe is presented. Besides, the chapter compares MDE software migration versus traditional migration processes as well as it describes the existing challenges to achieve the results in real projects in the scientific and industrial field.

BACKGROUND

Model Driven Engineering (MDE) is a software development approach that focuses on the use of models to define software development processes with a high degree of automation starting from reusable transformations between models that conform to metamodels. The underlying idea in MDE is that software development can be broken down into standardized, highly automated activities that can mass produce software applications reducing costs, development time and risks.

Different acronyms are associated with model-driven developments: MBE (Model Based Engineering), MDE (Model Driven Engineering), MDD (Model Driven Development), MDA (Model-Driven Architecture), MDSM (Model Driven Software Modernization) and ADM (Architecture Driven Modernization).

MBE is the branch of software engineering in which software models play an important role, being the basis of development. However, there is no direct link between the models and the generated software precisely defined through transformations.

MDE can be viewed as a subset of MBE. It is the branch of software engineering in which processes are driven by models, i.e. models are the primary artifacts of different software processes. MDE has emerged as a new software engineering discipline which emphasizes the use of models and model transformations to raise the abstraction level and the degree of automation in software development. Productivity and some aspects of the software quality such as maintainability or interoperability are goals of MDE.

MDD refers to forward engineering processes that use models as primary development artifacts. A specific realization of MDD is MDA (MDA, 2014). The outstanding ideas behind MDA are, separating the specification of the system functionality from its implementation on specific platforms, managing the software evolution from abstract models to implementations. Models play a major role in MDA, which distinguishes at least:

- Computation Independent Model (CIM), a model that describes a system from the computation independent viewpoint
- Platform-Independent- Model (PIM), a model with a high level of abstraction that is independent of any independent technology,
- Platform-Specific-Model (PSM) a tailored model to specify the system in terms of the implementation constructs available in one specific platform

The Unified Modeling Language (UML) combined with the Object Constraint Language (OCL) is the most widely used way for writing PIM and PSMs.

An MDA process focuses on the automatic transformation of different models that conform to MOF metamodel, the standard for defining metamodels in the context of MDA (MOF, 2016). It provides the ability to design and integrate semantically different languages such as general-purpose languages, DSLs and modeling languages in a unified way. MOF can be considered the essence of MDA allowing different kinds of artifacts from multiple technologies to be used together in an interoperable way. MOF provides two metamodels EMOF (Essential MOF) and CMOF (Complete MOF). EMOF favors the simplicity of implementation over expressiveness. The OMG standard related to model transformation is the MOF 2.0 Query, View, Transformation (QVT) metamodel (QVT, 2016).

In the context of ADM, a set of modernization specifications is developed. ADMTF is developing a set of standards of which we are interested in KDM (Knowledge Discovery Metamodel) and ASTM (Abstract Syntax Tree Metamodel) (ASTM, 2019) (KDM, 2019). KDM is a metamodel for knowledge discovery in software that allows representing information related to existing software assets, their associations, and operational environments regardless of the implementation programming language and runtime platform. KDM is the foundation for software modernization representing entire enterprise software systems, not just code. ASTM is a specification for modeling elements to express abstract syntax trees. KDM and ASTM are two complementary modeling specifications. KDM establishes a specification that allows representing semantic information about a software system, whereas ASTM establishes a specification for representing the source code syntax by means of AST (Abstract Syntax Tree) in a representation that is sharable among multiple tools. ASTM acts as the lowest level foundation for modeling software within the OMG ecosystem of standards, whereas KDM serves as a gateway to the higher-level OMG models.

MDSM is a particular form of reengineering for the technological and functional evolution of legacy systems that begins to be identified in the early 21st century (Brambilla et al., 2017). It is based on model-driven processes of reverse engineering, restructuring and forward engineering. Software reengineering distinguishes different levels of analysis and provides foundations for logical transformations at different abstraction levels, especially for transformations that can be of different types: T2M (Text-to-Model), M2M (Model-to-Model), or M2T (Model-to-Text).

The Eclipse Modeling Framework (EMF) was created for facilitating system modeling and the automatic generation of Java code (EMF, 2019) (Steinberg et al., 2009). EMF started as an implementation of MOF resulting Ecore, the EMF metamodel comparable to EMOF. EMF has evolved starting from the experience of the Eclipse community to implement a variety of tools and to date is highly related to MDD. In this context, the subproject Model to Model Transformation (MMT), hosts model-to-model transformation languages. Transformations are executed by transformation engines that are plugged into the Eclipse Modeling infrastructure. For instance, Atlas Transformation Language (ATL) is a model transformation language and toolkit that provides ways to produce a set of target models from a set of source models (ATL, 2019). Another subproject is Acceleo, which is an implementation of the Model-to-Text (M2T) transformation standard of the OMG for EMF-based models (Acceleo, 2019). Acceleo is used in forward engineering processes.

Today, the most complete technology that support ADM is MoDisco, which provides a generic and extensible framework to facilitate the development of tools to extract models from legacy systems and use them on use cases of modernization. As an Eclipse component, MoDisco can integrate with plugins or technologies available in the Eclipse environment (Modisco, 2019) (Bruneliere et al., 2014). In particular, the ASTM specification mainly includes the following metamodels:

- Generic Abstract Syntax Tree Metamodel (GASTM), a generic set of language modeling elements common across numerous languages establishes a common core for language modeling.
- Language Specific Abstract Syntax Tree Metamodels (SASTM) for particular languages such as Ada, C, Fortran and Java, that are modeled in MOF or MOF compatible forms.
- Proprietary Abstract Syntax Tree Metamodels (PASTM), that express ASTs for languages such as Ada, C and COBOL modeled in formats that are not consistent with MOF, the GSATM, or SASTM and define the minimum conformance standards needed to support model interchange.

In particular, C++ is one of the most commonly used programming language in science and engineering domains and numerous legacy software components written in C++ require to be modernized. EMF4CPP is the first step at providing a set of tools for MDD in C++ as an alternative to the Eclipse tools for Java (EMF4CPP, 2016). It is a C++ implementation and type mapping for the EMF core, the Ecore metamodel. The main facilities provided by EMF4CPP are to generate C++ code from Ecore metamodels and to parse and serialize models and metamodels from and into XMI documents (Jäger et al., 2016). However, an implementation of a MOF-compliant C++ metamodel is necessary for other MDE processes, in particular ADM (e.g., reverse engineering or software modernization).

Multiplatform Development

Today, one of the major challenges for software developers is dealing with the rapid proliferation of mobile platforms that entails the high cost, technical complexity, and risk of targeting development to a wide spectrum of platforms. Taking into account the diversity of platforms, which are also in a dizzying evolution, it is practically intractable defining as many metamodels and transformations as mobile platforms exist. To address this problem a possible solution is to have different teams of developers who are fluent in specific programming language to port an application to a specific platform. Instead of this traditional approach, organizations can use multiplatform or multi-paradigm cross-compiler based languages. In this context, the term “*multiplatform*” is used to refer source-source compilation, that is to say, the source code of these languages can be compiled into source code of other programming language. In this direction, the Haxe language emerges as an open-source high-level multiplatform programming language and compiler that can produce applications and source code for many different platforms from a single code-base.

The Haxe programming language is a high level programming language that mixes features of object oriented languages and functional ones. It is similar (but not pure) to object-oriented languages. Haxe includes a set of common functions that are supported across all platforms, such as numeric data types, text, arrays, binary and some common file formats (Haxe, 2019).

To date, Haxe supports nine target languages which allow for different use-cases: JavaScript, Neko, PHP, Python, C++, ActionScript3, Flash, Java and, C# and test your app on each platform. The Haxe language can be used in a variety of domains such game development, web development and mobile development. In particular, it facilitates mobile development sharing code between key platforms and accessing native functionality without sacrificing performance. The idea behind Haxe is to allow developers choose the best platform for a specific development. To achieve this, it provides a standardized language, a standard library that works the same on all platforms and platform specific libraries that allow accessing the full API for a given platform from Haxe.

Related Work

The first results that address MDE and mobile developments are specifically linked to MDD. A survey of MDD approaches for mobile applications is presented in (Umuhoza and Brambilla, 2016). Various authors describe the challenges of mobile software development. A DSL (Domain Specific Language), named MobDSL, to generate applications for multiple mobile platforms is described in (Kramer, Clark and Oussena, 2010). They perform the domain analysis on two cases in the Android and iPhone platforms. This analysis allows inferring the basic requirements of the language defined by MobDSL. From another angle, Dehlinger and Dixon (2011) highlight creating user interfaces for different kinds of mobile devices, providing reusable applications across multiple mobile platforms, designing context-aware applications and handling their complexity and, specifying requirements uncertainty. On the other hand, a proposal for supporting mobile application development by using models as inputs to an emulator is outlined at (Bowen and Hinze, 2011). The authors describe an MDD-based emulator for using in the design of graphical interfaces and interactions. They propose to transform functional behavior and requirement models with design restrictions into emulated applications. From another perspective, Acerbis et al. (2015) describe a comprehensive tool suite called WebRatio Mobile Platform for model-driven development of mobile applications. It is based on an extended version of OMG standard language called IFML (Interaction Flow Modeling Language) empowered with primitives tailored to mobile systems that enable specification of mobile-specific behaviors.

The following authors show integration of reverse engineering MDE. Favre (2010) describes a reverse engineering approach that fits with MDD. A framework to integrate different techniques that come from compiler theory, metamodeling and formal specification is presented. It emphasizes the use of static and dynamic analysis for generating MDA models. Fernández Candel et al. (2019) describe a model-driven reengineering approach for migrating PL/SQL triggers to Java-based on KDM to represent legacy code and traditional techniques to complement ADM. Test Driven Development (TDD) is used to incrementally develop model transformations that were written in Java instead of using some transformation language like ATL or QVT imperative. A systematic literature review on model-driven reverse engineering approach may be found at (Raibulet et al., 2017)

The following authors relate smartphones and mobile development with new technologies such as Cloud Computing and IoT. Islam and Want (2014) describes major trends affecting future smartphone design and use such as personal computers, the IoT, multimedia delivery, low power operation, wearable computing and context awareness. On the other hand, Ejarque, Miccsik and Badia (2015) present a solution for facilitating the migration of applications to the cloud, inferring the most suitable deployment model for the application and automatically deploying it in the available Cloud providers. The findings of experiments carried out to understand the impact of application characteristics, cloud and architecture and the android emulator used, on application performance when the application is augmented to the cloud, are shown at (Joshi et al., 2015). Gonzalez Garcia et al. (2015) define a domain-specific language (DSL) that allows specifying the coordination and communication between different types of smart objects.

Several works highlight research directions and challenges on the IoT. The spectrum of research needed to achieve IoT on a large scale requires research along with many different directions. Stankovic (2014) identifies five prominent research communities that involve the smart vision of the world: IoT, mobile computing, pervasive computing, wireless sensors, networks, and cyber-physical systems. Zanella et al. (2014) present a discussion of the IoT for smart cities. The authors describe a general reference framework for the design of an urban IoT. An implementation of an urban IoT that has been realized in the city of Padova is described. Key research topics are enumerated and research problems within these

topics are discussed. Miranda et al. (2015) propose an infrastructure that supports the evolution from the “Internet of Things” to the “Internet of People” (IoP). The IoP is used in the sense of bringing the IoT closer to people, for easily integrate them and exploit its benefits.

The following articles are directly related to the chapter proposal. A reengineering process that integrates traditional reverse engineering techniques such as static and dynamic analysis with MDA is presented at (Améndola and Favre, 2013). The article describes a case study that shows how to move CRM (Customer Relationship Management) applications from desktop to mobile platforms. The proposal was validated in the open source application platform Eclipse, EMF, EMP, ATL, and Android platform. Diaz Bilotto and Favre (2016) describe a migration process from Java to mobile platforms through the multiplatform language Haxe. A framework for modernizing desktop software based on MDE is presented at (Favre, 2018).

INTEGRATING MDE WITH FORMAL METHODS AND CROSS-PLATFORM DEVELOPMENT

This section describes the main focus of the article: the construction of metamodels starting from the integration of MOF-compliant metamodels and formal specification, and a migration process of non-mobile software to different mobile platforms based on MDE, ADM, and Cross-Platform Development.

Formalizing MOF-Compliant Metamodels

An essential aspect to apply this approach is to have reliable definitions of metamodels. It is important to formalize and reason about MOF metamodels and we propose to exploit the strong background achieved by the community of formal methods. It is important to remark that the instantiation of a metamodel produces models, which in turn are instantiated. So, having errors in a metamodel leads to having errors in its model instances. Besides, a model can be well-formed but still be incorrect. A combination of MOF metamodeling and formal specification can help metadesigners to address these issues.

A major obstacle for specifying metamodels MOF or Ecore is that they must master two different languages: UML for expressing class diagram that capture the structure of the domain and the OCL language for expressing associated semantic (OCL, 2014). Cadavid et al. (2015) observe that, in general, the metamodels concentrate the specifications in a subset of concepts, most of them are loosely coupled to the underlying structure. Most MDE semiformal metamodels do not have support for typing metamodels and the notion of polymorphism at the metamodel level is imprecise due to the type of a metamodel is not defined. These are important limitations regards to the generation of valid instances to test models transformations and to reuse models, metamodels and model transformations.

To address these problems, a formal metamodeling language called Nereus was defined. Formal methods offer rigor and precision while reducing ambiguity and inconsistency. Nereus allows specifying MOF or Ecore metamodels and reasoning about them. A detailed description of Nereus may be found at (Favre, 2009) (Favre and Duarte, 2016). A set of Nereus tools to make formal metamodeling feasible in practice was developed. The semantic of Nereus was given in the CASL language that can be linked with Automatic Theorem Provers (ATP) provided by Hets (Mossakowski, Maeder, and Codescu, 2019).

The process of meta-model construction is based on the analysis of fragments of models (examples of concrete instances) from which a metamodel is induced. These fragments focus on some interest aspects of the metamodel. In a first step, they are represented as an Ecore metamodel complemented with

textual specifications in *OCLinEcore* Editor that overcomes some limitations of the Ecore Editor, for instance, Ecore does not detect syntactic and semantic errors in OCL constraints. Another advantage is that *OCLinEcore* works with text representations instead of using *XMI* (XML Metadata Interchange), allowing greater modifiability, readability and better integration with versioning tools. A metaclass is created for each object of a different type (if it does not exist) and the attributes and operations and their restrictions are identified. Then, the different relationships between metaclasses are identified. The metamodel is subsequently transformed into a Nereus metamodel. The formal specification is analyzed by using the analyzer of Nereus and is modified according to the results of the translation process with the goal of obtaining a syntactically correct specification that, through its integration with CASL could be formally validated.

The typical flow with formal tools that is applied to analyze the specifications of metamodel is shown in Figure 1. In the first step, a semiformal metamodel is transformed into a Nereus specification. The formal specification is analyzed and modified according to the results of the translation process. The goal is to obtain a syntactically correct specification that, through its integration with CASL language can be formally validated. Nereus allows us to experiment both defining metamodels for DSLs from scratch, and analyzing fragments of already defined metamodels, detecting inconsistencies and proposing solutions.

Figure 1. Constructing metamodels

In the context of this work, the Haxe metamodel and C/C++ metamodel were defined. Figure 2 partially shows the C / C++ metamodel (on the left) and the Haxe metamodel (on the right).

Figure 2. C/C++ and Haxe Metamodels

The C++ metamodel conforms to Ecore. The root metaclass is *Program* that represents a C++ program, which owns source files, instances of *TranslationUnit*. A translation unit contains declarations such as block declaration, function definitions, template declarations, among others. A *SimpleDeclaration*, instance of *Block-Declaration*, has a *DeclSpecifierSeq* that is a sequence of *DeclSpecifiers* which refers to a declaration specifiers and a type specifier. In addition, a simple declaration has an *InitDeclaratorList* containing a variable declaration list that is a list of specifiers and the name of a variable and its corresponding initialization. A *FunctionDefinition* has a *Declarator* containing the function identifier and the parameter list. *Function* and *CtorOrDestFunction*, instances of *FunctionDefinition*, have a body that contains compound statements such as declarations, iterations, and selections. In addition, a *Function* has a *DeclSpecifierSeq* that is a sequence of *DeclSpecifiers* such as function specifiers and a type specifier. *TypeSpecifier* subclasses are *SimpleTypeSpecifier*, *ClassSpecifier* and *EnumSpecifier* among others. A *ClassSpecifier* has a *ClassHead* containing the class key (class or struct) and a *MemberSpecification* that contains *MemberDeclarations* such as variables, function declarations, function definitions, constructors, destructor and template members.

Also, the Haxe metamodel was defined in Ecore. The main metaclasses of the Haxe metamodel are those that allow specifying an application using Haxe as language. One of the main metaclasses of the

metamodel is *HaxeModel* that serves as element container used to describe an application and store additional information on it, for example, some options of compilation and different metaclasses for modeling such as modules, classes and packages. The metaclasses used directly by *HaxeModel* are *HaxeModule* and *HaxePathReferentiable*. Starting from the relations *HaxeModules*, *referenced* and *elements*, the class *HaxeModel* allows storing different information. Relation *HaxeModules* allows accessing the different Haxe modules used in the project. Through relation *elements*, it is possible to access the different elements of the package tree. Relation *referenced* provides access to elements which are referenced in the project but are not defined completely. In the case of relations and referenced elements, the type used is *HaxePathReferentiable*, which is the parent type of metaclasses such as *HaxeType* and *HaxePackage*. The Haxe language includes different kind of types such as class (the type's class and interface), function, abstract type, enumeration, and anonymous structures. A full description of both, the C/C++ and Haxe metamodels may be found at (Duthey and Spina, 2016).

Migrating Software to Mobile Platforms

A process to migrate legacy code to different mobile platforms based on ADM standards and cross-platform development is described. The migration process follows model-driven development principles: all artifacts involved in the process can be viewed as models that conform to Ecore meta-metamodel, the process itself can be viewed as a sequence of model-to-model transformations and the extracted information is represented in a standard way through Ecore metamodels. For each transformation, source and target metamodels are specified. A source metamodel defines the family of source models to which transformations can be applied. A target metamodel characterizes the generated models. Different kind of transformations such as T2M, M2M, and M2T are distinguished in the steps of reverse engineering, refactoring/restructuring, and forward engineering. Figure 3 summarizes the proposed process.

Figure 3. The migration process

The first step is the reverse engineering of source code to obtain the abstract syntax tree of the code and consists of two stages:

- Generating the first model of the code by using a model injector. This model conforms to the source code metamodel, such as C++ and Java. The obtained model could be refactored to reorganize and modify the syntactic elements and to improve the design. The refactoring is implemented as a model-to-model transformation whose source and target models are instances of source code metamodel.
- Generating the abstract syntax tree model, instance of the GASTM metamodel, from the model obtained in the previous stage by an ATL model-to-model transformation.

In this first step of the process, an injector and a transformation to obtain the GASTM model must be implemented for each language, whereas the sequence of transformations involved in the followings steps of the migration process is independent of the language of the legacy code.

The second step generates the KDM model. This process is carried out by means of an ATL model-to-model transformation that takes as input a model conforming to the GASTM metamodel and produces a model conforming to the KDM metamodel.

The advantage of this intermediate step is that starting from the KDM model it is possible to obtain high-level models such as UML class diagrams, activity diagrams and use cases diagrams. These models could be refactored and be the starting point for generating code. This step is common for each source language.

UML models generated from KDM are transformed to UML models for the Haxe platform from which it is possible to generate Haxe code using M2T transformations expressed in Acceleo (Acceleo, 2019).

Given that Modisco provides T2M transformations for Java, we will discuss the stages for the migration of C++ code to different mobile platforms.

The first transformation extracts an AST model specific to C++ from code. To carry out this task, we constructed a model injector by using EMFText (EMFText, 2019). To generate this injector, EMFText requires the language metamodel and the concrete syntax specification. In our approach, to generate the injector we first specified the C++ metamodel based on the C++ grammar. Then, we specified the concrete syntax that defines the textual representation of all metamodel concepts. Taking these specifications, the EMFText generator derives an advanced text editor that uses a parser and printer to parse language expressions to EMF models or to print EMF models to languages expressions respectively.

The second transformation takes as input the model obtained in the previous step and release a generic AST model conforming to the GASTM metamodel. This transformation specifies the way to produce GASTM projects (target) from C++ programs (source). The previous transformations are dependent on the legacy code language, that is, the model injector and the transformation to obtain the generic AST model are dependent on C++. In contrast to the previous stage, the sequence of transformations from GASTM models to Haxe models is independent of the language.

Haxe allows writing mobile applications that target all major mobile platforms in a straightforward way. The generated code is syntactically correct, although, it does not compile on other platforms without doing changes due to the code refers to proprietary technologies of C++. To run on mobile environments, these technologies can be replaced with OpenFL and HaxeUI (that is an open-source, multi-platform application-centric user interface framework designed for Haxe and OpenFL) (OPEN FL, 2019)

SOLUTIONS AND RECOMMENDATIONS

The previous sections describe two main contributions:

- The migration of object-oriented software to various platforms based on the integration of ADM with Haxe.
- The construction of metamodels based on the integration of semiformal and formal specifications.

With respect to the first contribution, it is possible to migrate the logic of software applications and run them on mobile platforms without having to completely rewrite them. Due to the fact that the objective of the migration is not only “compile” an application in a mobile platform but also to create a fully functional version of the application using quality criteria, small adjustments had to be made.

MDE approach based on ADM provides benefits with respect to ad-hoc migration. One of the benefits is to increase productivity in software development due to the automation that is introduced in the generation of artifacts. In MDE migration projects is more cost-effective when the same process must be repeated frequently as the case of migrations to different platforms.

Another benefit of the process is its independence from source and target technologies. In our approach, the intermediate models act as decoupling elements between source and target technologies. Independence is achieved with injectors and, M2M and M2T transformations. Besides, in a transformation sequence, models could be an extension point to incorporate new stages, for instance, to connect with different multiplatform languages. Model transformations allow developers to concentrate on conceptual aspects of the relations between models and then to delegate most of the migration process to the transformation rules, whereas in the brute-force redevelopment, developers need to migrate by hand the legacy systems, making over and over again the same task.

In the context of our proposal, Haxe allows using the same code to deploy an application on multiple mobile platforms. The migration of object-oriented software to mobile platforms is achieved through the definition of a metamodel for Haxe and a single M2M transformation, delegating the integration with different mobile platforms to Haxe, that is, the evolution of existing platforms or the integration of new mobile platforms is considered a goal of Haxe.

The following limitations our approach were observed. The set of metamodels and discovers that can be used is limited. In our approach, it was necessary to define metamodels for the C / C ++ and Haxe languages and, a discoverer for C/C ++. However, the cost of preliminary activities could be recovered in later developments.

With respect to the second contribution, a metamodeling framework based on MOF and the algebraic formalism that focuses on automatic proofs and tests was provided. The central components of our approach are the definition of the formal language Nereus closed to MOF and the development of tools for formal metamodeling: the Nereus analyzer and the Nereus-to-CASL translator.

FUTURE RESEARCH DIRECTIONS

Figure 3 shows the essential activities to migrate non-mobile software to various mobile platforms. The different stages were validated in medium-scale developments. However, each stage requires more research and experimentation to show the real impact on larger scale developments.

A semiautomatic tool that takes as its starting point a C++ project and produces one written in Haxe, in addition to the generated intermediate files, was developed to prove model transformations. The tool is semi-automatic because it requires additional actions on the Haxe code to make it fully functional (Duthey and Spina, 2016). It is also still a challenge to migrate the visual part if the graphical interfaces are linked to specific libraries. The tool has been used in the migration of games such as Tetris and medium-scale software applications.

Also, it remains to analyze the generation of Haxe code from UML models more deeply. Considering that from KDM it is possible to generate UML models at the PIM level and that currently, CASE MDA / UML tools do not support multiplatform languages it is necessary to move from the stage of validation of transformations through prototypes to a real integration with existing CASE tools, either commercial or free.

An important contribution was to achieve an infrastructure to define metamodels rigorously. It remains to be completed the integration between formal metamodels and Ecore metamodels through the automatic generation of Ecore metamodels from Nereus metamodels.

CONCLUSION

An ADM approach for migrating non-mobile software to different mobile platforms was described. It takes advantage of tools emerged in the cross-platform and formal methods communities. The transformation to different platforms is achieved with the definition of a metamodel for Haxe. It is important to note that was not necessary to define metamodels for all the languages and platforms supported by it, as it would have been necessary in order to realize a “pure” MDE development.

An infrastructure for the definition of metamodels based on the integration of semi-formal and formal specifications was described. It was validated with the definition of two metamodels: the Haxe metamodel and C/C++ metamodel, previously non-existent.

Another contribution to the MDE community is the definition of a set of T2M, M2M and M2T transformations that support the migration process and can be reused in other MDE processes. Considering that mobile application developers need frequently adapt software components and applications developed in languages such as Java or C/C++, the model-driven migration processes could be reused and the cost of preliminary activities would be recovered.

KEY TERMS AND DEFINITIONS

ADM (Architecture Driven Modernization): The process of understanding and evolving existing software assets of an existing system in the context of MDA.

ATL (Atlas Transformation Language): A model transformation language and toolkit developed on top of the Eclipse platform that provides ways to produce target models from source models.

Ecore Metamodel: The de-facto reference implementation of EMOF (Essential Meta-Object Facility), a subset of MOF. It is the core metamodel of EMF.

Haxe: An open-source toolkit based on a modern, high level, strictly typed programming language, a cross-compiler, a complete cross-platform standard library and ways to access each platform's native capabilities.

KDM (Knowledge Discovery Metamodel): The core metamodel of ADM, a language-independent metamodel for representing assets of software legacy.

Metamodeling: The process of generating a “model of models”; the essence of Model Driven Development approaches.

Mobile Technology: The technology used for cellular communication.

Model Transformation: A mechanism for automatically creating target models based on information contained in existing source models

Model-Driven Architecture (MDA): An initiative of the OMG for the development of software systems based on the separation of business and application logic from underlying platform technologies. It is an evolving conceptual architecture to achieve cohesive model-driven technology specifications.

Model-Driven Engineering: Software engineering discipline that emphasizes the use of models and model transformations to raise the abstraction level and the degree of automation in software development.

Software Migration: A kind of modernization for moving from the use of one operating environment to another operating environment that is, in most cases, thought to be better.

Interaction Speed as Nonverbal Cues in Text Messaging via Smartphone

INTRODUCTION

Computer-mediated communication (CMC) has the ability to bridge people across time zones and geographic regions (Kiesler & Sproull, 1992), thereby removing temporal and spatial barriers to interpersonal communication (Hesse, Werner, & Altman, 1988; Noman, 1983). Indeed, by using the Internet, people can communicate anytime, anywhere. Especially in text-based asynchronous forms of communication, such as email and electronic message boards, users can communicate at their convenience (Christie & de Alberdi, 1985; Katz & Aakhus, 2002; Tyler & Tang, 2003). However, this freedom from temporal restrictions—one of the two barriers relieved by CMC—has been weakened by the recent advent of mobile text-messaging (Kato, Kato, & Usuki, 2019; Murtagh, 2002). Expansion of communication devices from PCs to mobile phones and smartphones has greatly contributed to this (Kato & Kato, 2015). For example, people looking at their phones while walking is now a common sight on the street and in train stations (Lamberg & Muratori, 2012; Pešić, Antić, Glavić, & Milenković, 2016). Although they do so for a variety of reasons, it seems likely that many are texting while walking in order to quickly reply to received messages (Lim, Amado, Sheehan, & Van Emmerik, 2015; Schwebel, McClure, & Porter, 2017). In text messaging with mobile phones and smartphones, many users face pressure to rapidly reply (Kato et al., 2019; Kato & Kato, 2015, 2016). Despite the increasing importance of mobile text-messaging, few studies have examined reply speed. This article explores the roles played by reply speed in smartphone messaging, specifically focusing on messaging apps that include a read receipt function (i.e., a function that notifies the sender of whether a recipient has read a message) (Kato, Kato, & Ozawa, 2017). Additionally, this article discusses interaction speed as a form of nonverbal cue in text messaging.

BACKGROUND

Early studies of Internet-related psychology cited a lack of nonverbal cues and visual anonymity as characteristics of text-based communication on PCs (Joinson, 2003). A number of studies on CMC have discussed these characteristics of text-based CMC exchanges in terms of the absence of facial expressions, gestures, and nonverbal cues such as tone of voice that are involved in face-to-face conversation

DOI: 10.4018/978-1-7998-3479-3.ch062

(Kiesler, Siegel, & McGuire, 1984). These characteristics form the basis of various models and theories in CMC research conducted prior to the 1990s. For example, the social presence model (Short, Williams, & Christie, 1976) posited that when media conveys little nonverbal information, the sense of the other party as an actual person becomes less distinct—resulting in cold, impersonal communication. In media selection, media richness theory (Daft & Lengel, 1984; Daft & Lengel, 1986) recommended using rich media that can transmit information sufficient for unequivocal communication. The cuelessness model states that because CMC lacks the nonverbal cues that are present in face-to-face communication, communication tends to become task-oriented rather than socioemotional (Rutter, 1984; Rutter, 1987; Rutter, Stephenson, & Dewey, 1981). The reduced social cues approach says that in CMC lacking nonverbal information, users experience depersonalization, which results in uninhibited communications and consequently a higher probability of behaviors that are outside of social norms (McGuire, Kiesler, & Siegel, 1987; Siegel, Dubrovsky, Kiesler, & McGuire, 1986; Sproull & Kiesler, 1986).

An active area of CMC research in the 1980s was the exploration of the consequences of this deficiency. However, subsequent CMC studies have shown many examples of socioemotional communication that can deepen personal relationships, even in text message exchanges that contain few nonverbal cues (Walther, 2011). For instance, more self-disclosure is thought to occur in CMC (Joinson, 2001; Matheson, 1991; Matheson & Zanna, 1988). With few nonverbal cues, visual anonymity is preserved and de-individuation occurs, which attenuates the restraint typically exercised during face-to-face communication. Also, according to the hyper-personal model (Walther, 1996), the dearth of nonverbal cues in CMC permits interactions that are closer to the idealized self. For example, users can make controlled, selective presentations of themselves to the other party in a way that facilitates creating a favorable impression. These studies provided examples of the skillful employment of minimal nonverbal cues in CMC (Walther & Tidwell, 1995).

Research conducted over the last two decades reveals the importance of chronemic nonverbal cues in CMC, and how chronemics influence online interaction (Kalman, Scissors, Gill, & Gergle, 2013). These studies explored the influence of chronemic variables such as the time of day or length of the pause preceding a response on impression formation during online interactions (Döring & Pöschl, 2008; Kalman et al., 2013; Kalman & Rafaeli, 2011; Sheldon, Thomas-Hunt, & Proell, 2006). For example, Ballard and Seibold (2004) described how chronemics are a core component of human communication. Sheldon et al. (2006) focused on perceptions of delays in online replies and found that a delayed response by a high-status respondent was interpreted more positively than the same delay by a low-status respondent. Responsiveness is an important aspect of communication, and we are attuned to identify even slight delays in responsiveness. Such delays often lead to negative consequences, such as being perceived as less socially competent (McLaughlin & Cody, 1982). An experimental study revealed that the same task-related e-mail message was perceived as more assertive when sent at night than when sent during the day (Walther & Tidwell 1995). Short response times can be interpreted as nonverbal cues of interpersonal closeness, immediacy, care, presence, and even submissiveness (Döring & Pöschl, 2008). In summary, previous research on chronemics has been mainly confined to the context of users' impression formation during PC-based communication.

NONVERBAL CUES IN TEXT MESSAGING VIA MOBILE PHONE

Most early CMC research focused on Internet-mediated communication via PCs. However, many people now use mobile phones or smartphones to communicate over the Internet. Communication using such

devices differs from PC-based communication in several ways (Döring & Pöschl, 2008). For example, emoticons and emoji are used more frequently in text-based communication that occurs via mobile phones than in PC-based communication (Tossell, Kortum, Shepard, Barg-Walkow, Rahmati, & Zhong, 2012). Additionally, text messaging on mobile phones tends to be briefer and more interactive than PC-based communication (Mahatanankoon & O'Sullivan, 2008). The lack of nonverbal information in text-based communication has been the subject of much CMC research. However, now that mobile phones have come to play a major role in communication, response times can be thought of as conveying important nonverbal information (Kalman & Rafaeli, 2011). For example, a “slow” response might nonverbally convey negative emotion (Kalman et al., 2013). Acknowledging this potential negative cue, slow e-mail replies often contain apologies and explanations to compensate for the extended response time (Kalman & Rafaeli, 2011; Kalman, et al. 2013). In other words, the speed of interaction via PCs provides information that influences impression formation, such as of the user's individual characteristics, but the speed of mobile interaction provides more real-time information on emotional and psychological states.

In most text-based communication, including conventional email, there is no interaction while the message sender awaits a reply. However, messaging apps such as Facebook Messenger, WhatsApp, and LINE (an instant messenger application for smartphones, used mainly in Japan) have “read receipt” functions that notify senders when recipients have read a message, thereby allowing the sender to know that the recipient has read the message, even before any reply arrives (Hoyle, Das, Kapadia, Lee, & Vaniea, 2017; Kato et al., 2017). In such exchanges, many senders will be concerned not only about the time spent waiting for a reply, but also the time until the read receipt appears (Kato et al., 2017). One reason for this is that the sender may suspect that the recipient is ignoring the message if the read receipt is not displayed after an extended time (“ignored unread”) or if no reply is received long after the read receipt has been displayed (“ignored read”). Conversely, recipients may worry about their intentions being misunderstood if messages are left in an “ignored unread” state when messages cannot be read immediately, or in an “ignored read” state when unable to immediately reply to read messages. This psychological pressure is becoming problematic, especially among young users (Hoyle et al., 2017; Kato, Kato, & Ozawa, 2018; Kato & Kato, 2016).

From their presumed desire for a quick reply, it can be said that the sender is in a dominant position in smartphone-based text messaging (Kato et al., 2018). For example, message recipients may feel pressured to reply quickly so as to avoid causing anxiety in senders awaiting a response (Kato & Kato, 2015). However, reply speed is an operable nonverbal cue. Furthermore, as an addition to reply speed, text messaging with a read receipt function informs the sender whether a message has been read (Hoyle et al., 2017; Kato et al., 2017). This function, too, can be thought of as a nonverbal cue through which recipients can intentionally convey psychological meaning. Namely, in text messaging, where the sender's position dominates that of the recipient as described above, the reply speed and the read receipt function may provide strong nonverbal information that the recipient can manipulate. Strategic use of the read receipt is a nonverbal cue that enriches socioemotional interaction.

SOLUTIONS AND RECOMMENDATIONS

As the read receipt function continues to be adopted by additional smartphone messaging apps, our textual interactions are likely headed toward new temporal restrictions unlike those experienced during the initial spread of CMC. Restricted communication such as CMC offers individuals the ability to communicate more strategically (Walther & Parks, 2002). Kato et al. (2017) suggested that the emotional

states of individuals waiting for a reply can be affected by reply speed. Rapid exchanges of text messages in asynchronous media will eventually lead to frequent message exchanges and be positively related to the maintenance of socioemotional relationships (Walther, 1992). Therefore, quick replies in messaging serve strategic relational maintenance functions (Brody, Mooney, Westerman, & McDonald, 2009). However, it is possible to strategically manipulate reply speeds to elicit negative emotions in individuals waiting for a reply. For example, if a sender want to keep a romantic partner in anticipation through replying slowly, it might be more effective to let the partner wait with the message in read status than in unread status. This example is only one possibility, and strategic control of reply speed in messaging with a read receipt function is an interesting topic for future research. However, some studies make clear the possibility that reply speed in messaging with a read receipt display serves a role as a nonverbal cue that can affect senders' emotional states (Hoyle et al., 2017; Kato et al., 2017). These nonverbal cues are more difficult to interpret than are emoticons, so we must take care in attribution of meaning. Such cues may contain specific communicative intent in some cases, while in other cases there is no such intent—the delayed response is simply due to unavoidable circumstances that prevent a reply.

FUTURE RESEARCH DIRECTIONS

In this article, it was suggested that the speed of exchange and the display of read receipts in mobile text messaging have become new nonverbal cues. However, research has not yet evaluated strategies applied with these cues and their possible contribution to effective communication. Historically, various innovations have been made in text-based communication to alleviate constraints on expressing meaning, such as using emoticons composed of punctuation marks, letters, and symbols. Perhaps seasoned users of text messaging may already be using these new chronemic cues effectively. Therefore, insights may be gained via detailed analysis of seasoned users' behavior in terms of exchange speed and use of the read receipt function. In addition, it is necessary to verify the hypotheses concerning innovations obtained from observation and interview survey. Such data would assist researchers in formulating ideas aimed at modifying exchange speed and use of the read receipt function, which are now a source of psychological pressure for many users of text messaging applications.

Today, educational activities (e.g., Hossain, Nurunnabi, Hussain, & Saha, 2019; Hossain, Shan, & Nurunnabi, 2019) and businesses (e.g., Hossain, 2019) using mobile devices and smartphones have also become popular. In such situations, studying the effect of speed of interaction on effective learning and purchasing behavior is also a future issue. Additionally, previous research has pointed out that the recipient type, such as friendships, romantic relationships, and family relationships, influences demands for reply speed (Kato & Kato, 2015). In other words, it should be noted that the pressure for a quick reply varies depending on the recipient type. Finally, “read receipt functions” are functions added recently in mobile message texting, and this function speeds up the exchange of messages. The impact of new functions born through various upgrades on the speed of message exchange will change in the future. It will be necessary to keep an eye on the relationship between frequent updates on texting and chronemic nonverbal cues.

CONCLUSION

This article focused on the speed of interaction in text messaging via smart phone applications (especially those with read receipt functions). It was suggested that the speed of exchange and read receipt status can serve as operable nonverbal cues to the sender of the message. Toward the aim of effective communication via text messaging using smartphones, we propose future directions in examining the strategic use of speed of interaction and read receipts.

KEY TERMS AND DEFINITIONS

Digital Immigrants: Digital immigrants are the generations preceding digital natives, who initially used traditional media before gradually adopting new ICTs and services as they became available.

Digital Natives: Digital natives are born into an information/communications technology environment where the Internet, email, and mobile phones are commonly used.

LINE Application: LINE is an instant messenger that is similar to other internet-based messengers, such as WhatsApp, and is the most-downloaded social media/messenger application in Japan. The application was released in June 2011, following the Great East Japan Earthquake of March 2011, with the aim of creating an application where users can easily communicate even in the event of a disaster. In Japan, LINE has come to replace traditional mobile text messaging services (including SMS), especially among young people.

Read Receipt Status: A read receipt function automatically informs the sender that the recipient has read the message.

Speed of Reply: Although text messaging can easily exchange text messages, its users typically expect faster replies than with cell phone text messaging. In fact, the act of periodically checking one's smartphone for incoming messages happens daily.

Stickers: The sticker is a newer graphical element similar to emoji or emoticons that conveys emotional state, attitude, and opinion and is a small illustration that is sent in place of a message. The sticker originated as an attachment in LINE, but by 2013, Facebook Messenger was equipped with similar features, followed by Facebook timeline in 2014. In 2016, iMessage for iPhone added sticker functionality.

Unread Receipt Status: An unread receipt function automatically informs the sender that the recipient has not read the message.

Narrowband Internet of Things

INTRODUCTION

Internet of things (IoT) is pervasive extension of the Internet. It uses several sensors based on the application requirements for interconnecting them together in a common framework. These days IoT has several dimensions for numerous applications and it facilitates massive machine type communications. IoT has the ability to reach the territories where there is no Internet available. Internet is normally available where there the human settlements are present. However, there are many scenarios where we need the information without the presence of the Internet. For instance, measurements of under surface soil humidity and fertilizer intensity can be brought in to the Internet through the IoT. This can be done by deploying appropriate sensors under the earth surface. Similarly, there are applications in which micro monitoring is required in the unmanned territories. In those cases, the supervision of the IoT can be done through some remote communication nodes. IoT can provide the information from many unmanned locations using its sensors and the communication infrastructure of the Internet.

Background of NBIoT

IoT is now an integral part of the modern digital ecosystem and leading the changing trends in many sectors. It has several ramifications and can be applied to a number of sensor-based application scenarios. Initially, it was started as a value-added segment for the cellular communication networks. Gradually, they became very popular in many applications. Now they appear in several cellular and non-cellular forms including sensor networks, control networks, and independent networks. Different types of IoTs are available depending on their features. Narrowband IoT (NBIoT) is one of the standardized forms of IoT which is very attractive due to its suitable features. According to the name, NBIoT needs narrow band frequencies for its operations. This narrow band requirement is quite special for NBIoT and thus it has several advantages over other forms of IoTs. NBIoT has ability to cover a large area with a small amount of transmit power (Routray & Sharmila, 2017). This is an energy efficient feature of NBIoT which makes it a popular green technology. These days green and sustainable technologies have high demand due to their energy efficiency and environment friendly features (Zhu et al., 2015). In these quest, NBIoT like low energy technologies are very popular in different applications in which IoTs and sensor-based technologies are essential. Now green IoTs are well researched areas in which optimization of resources is a prime goal (Routray & Sharmila, 2017). In the resource limited situations, such as the developing countries, they have even more important roles due to the shortage of resources.

In the recent years, several works have been done on different types of IoTs to make them more energy efficient. In Routray & Sharmila (2017), green IoTs have been studied from several technological aspects. In that work NBIoT has been proposed as the inherent green technology for several applications due to its attractive energy and bandwidth saving features. In Zhu et al. (2015), energy efficient and sustainable

DOI: 10.4018/978-1-7998-3479-3.ch063

initiatives for IoT based smart world have been addressed. It provides several recent progressive trends on smart initiatives and technologies which are able to make the entire IoT networks energy efficient. It also gives insight for the segment-wise greening processes in the framework of existing information and communication technologies (ICTs) across different application domains. Perera et al. (2014), provided a comprehensive survey of the contemporary IoT marketplace of last few years. That survey explains the recent industrial demands and applications of IoT and its associated technologies in different industrial and other associated processes. They also elaborate through justified logic that manufacturing and automation will have a large share of industrial IoT. Da Xu, He, Li (2014) too provided a similar survey which focuses on the technological prospective of IoT. This survey emphasizes that the wide deployments need to be energy efficient for the practical reasons. In Al-Fuqaha et al. (2015), a comprehensive survey on the practical aspects of IoT such as the enabling technologies, protocols and applications have been presented. At first it deals with the enabling technologies that make IoT a reality and then show the main protocols which are instrumental in the IoT operations. Finally, it provides a long list of applications in which IoT can play significant roles. The authors pointed that the overall success of IoT is very much dependent on the efficiency of the entire IoT networks, their components and end devices. Ramnath et al. (2017) and Yu et al. (2016), provide the hybridization of IoT networks with other types of networks, such as the cellular networks for advanced applications like the localization and tracking of objects and living animals. In the later one the 5G IoT related localization has been emphasized using special algorithms.

The work of Mohanty and Routray (2017) presents the recent trends of consumer electronics driven data communication networks. This paper shows the volume of the resources, such as the bandwidth and power for transmission needed for the global communication networks. The data storage and communication infrastructure required for the current ICT sectors too have been presented in this article. Sustainability aspects of communication networks have been presented in Mohanty & Moreira (2014). In this paper, carbon emission contributions of global communication sector have been presented which shows that more than 2% global carbon emissions are from the ICT sector. Outlooks for overall sustainability in the ICT sector have been proposed in this work. Pirinen (2014), provide the research and development initiatives of 5G and IoT are presented in which energy efficiency and overall network optimizations are emphasized. Hossain et. al. (2012), present the fundamental aspects of green radio communication technologies and the emerging methods used in ICT sectors for energy efficiency. This work also provides insights for emerging networking technologies such as IoT for overall energy efficiency. Cavalcante et al. (2014), present 5G energy efficiency related aspects which mentions general system characteristics for overall effectiveness on the system. Anand & Routray (2017), present the applications scenarios of NB-IoT for healthcare. This work analyses several issues and challenges in the healthcare NB-IoT. Security aspects of IoT are quite challenging. In Routray et al. (2017) novel cryptographic techniques for IoT have been suggested. Quantum cryptography for IoT is a robust security for the long term. Standardization NB-IoT was started in LTE Release 13 (Ratilainen, 2016). Basic specifications of NB-IoT were established for the cellular NB-IoT. These standards were updated for enhanced performances in Release 14 (Hoglund et al., 2017).

In this article, we provide the main principles, potentials and applications of NB-IoT. We present its deployment issues and the commonly encountered challenges in its implementation. These days NB-IoT is very popular in several situations due to its attractive features. We show that NB-IoT is the right choice for the developing countries at the moment. We also address its main motivating features, deployment options, and applications in different sectors.

The remainder of this article is organized in three sections. In Section 2, we present the energy efficient and green characteristics of NB-IoT. We also presented its deployment options and applications of

NB-IoT in different sectors. In Section 3, we present the overall initiatives being taken in the recent times to make NB-IoT resource efficient. We showed its suitability for the developing countries. In Section 4, we conclude with the main points of this article.

General Features of NB-IoT

NB-IoT is the low energy and low bandwidth version of IoT which is designed for the massive machine-to-machine communications. As the name suggests, it uses narrow bands for its different functions and operations. It needs a bandwidth of just 180 kHz to 200 kHz for its designated processes. NB-IoT finds a special status in the recent standards of Third Generation Partnership Project (3GPP). In their long term evolution (LTE) Release 13 and 14, 180 kHz has been proposed as the operating bandwidth for NB-IoT. It is a low power wide area (LPWA) technology which can save a lot of power when compared with other forms of IoTs. It is good for large scale economical deployment of IoT for different applications. In true sense, it is leaner, thinner, and greener than other IoTs proposed in the recent years. It can be deployed in both the cellular and non-cellular forms. However, cellular forms are popular as they can use the existing cellular architectures for its operations. In LTE Release 13 and 14, it has been standardized according to the compatible LTE provisions and also proposed for connected living environments (Hoglund et al., 2017).

Basic LPWA Features of NB-IoT

NB-IoT is an energy efficient version of IoT. The main attraction of NB-IoT is its LPWA nature. It can save a large amount of energy and bandwidth of a network. Its architecture and protocols have been standardized in the recent releases of LTE for different environments. Deployment bandwidths of NB-IoT have been agreed by the standardization committee in Release 13. Depending on the situation, different spectral bands can be used by different operators. According to Release 13 of 3GPP LTE, the maximum usable bandwidth of an end device is 200 kHz. Generally, for the communication purpose 180 kHz is used (Routray & Sharmila, 2017). At this bandwidth, the upper limits of the uplink and downlink data rates are set at 150 kbps. In Release 13, half duplex mode has been recommended for NB-IoT communications. In Release 14, these specifications have been further enhanced for advanced applications. The power from the transmitter is kept quite small so that a single battery can supply power to the NB-IoT devices or nodes for more than 10 years. In fact, in the recent NB-IoT standards, two power levels have been specified: 20 dBm and 23 dBm (Routray & Sharmila, 2017). The sensitivities of the NB-IoT sensors are really good. They can receive the signal at a power level as low as -64 dBm. These are the exclusive features of NB-IoT which are not found in other versions of IoTs proposed so far.

NB-IoT Architecture

A systematic NB-IoT architecture is required for its planning, dimensioning, cost estimation, design and final deployment. NB-IoT does not have a legacy to follow as it is one of the earliest IoTs of its type. However, it is similar to the wireless sensor networks (WSNs) to some extent and the WSNs have been there for several years. The existing WSN architecture and topologies can be helpful in the design of NB-IoT and its further advancement. It is noteworthy that WSNs did not have a structured and well-defined architecture like the cellular systems, such as the LTE networks which will form the backbone of NB-IoT. Therefore, an LTE cellular framework for NB-IoT is the right choice at the moment (Hoglund

et al., 2017). The layered architecture of NB-IoT is helpful in its planning and deployment. In Release 13, several specifications for different layers have been mentioned. NB-IoT can be separated into six layers as shown in Figure 1. The physical layer is at the bottom and it is normally the air interface. Physical layer does the similar functions as in WSNs and some additional functions as defined in Release 13. Above it is the medium access control (MAC) layer. This has the similar functions like the MAC layer of other networks. It incorporates the protocols for medium access and multiple access techniques. There is a radio link control layer in between the MAC and the upper layers. This layer makes the adaptation of the MAC layer information for radio links. Above it is the packet data convergence protocol layer which provides routing, traffic scheduling, networking, and other related tasks. Then above it is the radio resource control layer which takes care of the radio resources of the packets in the channels. NB-IoT uses user datagram protocol (UDP) and other cellular mechanism to carry this function. UDP is effective in the wireless networks and thus suitable for NB-IoT as well. The topmost layer is the Non-Access Stratum (NAS) which establishes the communication between the user equipment (UE) and the main server of the NB-IoT, also known as NB-IoT central node. NAS also provides the security and privacy related operations to the UE.

Figure 1. OSI Model of NB-IoT with six layers architecture which follows the LTE design to a large extent

Deployment Options for NB-IoT

NB-IoT deployment options have been agreed in LTE Release 13. According to it, NB-IoT can be deployed in three different forms. The first being the standalone deployment in which an independent microwave band is provided in the 700MHz or 800 MHz range for its deployment. The second one is the guard band deployment in which the spectrum used for NB-IoT is the unused GSM and LTE guard bands. These guard bands are normally not used for communication purposes in GSM and LTE cellular systems. With the arrival of NB-IoT, these guard bands find a new application. The third one is the in-band deployment. In this case, some part of the GSM or LTE spectrum is allocated to the NB-IoT. In Fig. 2, we show these 3

deployment scenarios. In practice, either of them can be used depending on the availability of the bands and its suitability. If required, even two or all three options can also be used in specific cases.

Figure 2. NBIoT deployment options in different bands

Applications of NBIoT

NBIoT is attractive in the LPWA regime. It has tremendous potential to operate in the resource limited scenarios. Here, we shed the light on some of the typical sectors where it is currently considered for deployment. Several applications of NBIoT are possible and it can be deployed for any LPWA applications in which the all the relevant elements of IoT are available. Both local and nonlocal applications of NBIoT are equally possible. Emerging applications are found in several technology and social sectors with every passing month. There are several new sectors in which NBIoT has potential applications. Some of these applications are indoor and the others are outdoor. NBIoT can be instrumental in designing smart homes and smart cities (Routray & Sharmila, 2017). Similarly, it can help in healthcare as well as the security monitoring of public places. In Fig. 3, we present some typical sectors in which NBIoT can have significant role. These sectors are: smart city management and monitoring; smart home applications; large scale manufacturing; pet tracking; kids' tracking; healthcare monitoring; safety and security related applications; smart agriculture and farming; energy and utility management; automobile and vehicular management; retail management; policing and law enforcement assistance; detection of environmental degradation; waste management; and several other LPWA applications. In fact, for rural areas NBIoT is considered the only choice due to its economical features.

Figure 3. Different applications of NBIoT. New applications emerge every month in different sectors.

NBIoT for Agriculture

NBIoT can be deployed in the agricultural sector for several performance enhancement related aspects. In agriculture, several resources are used to increase the harvest. Many of those resources are under-utilized due to the lack of facilities to monitor their utilities. For optimal use of the resources, NBIoT can be used which can sense the level of utilization and improve the utilization efficiency. For instance, water is an essential resource for agriculture. It is not available in sufficient amount in every part of the world. In the dry areas, water has to be utilized very efficiently. This utilization can be monitored in the agricultural farms through the water sensors deployed under the soil. Similarly, fertilizer concentration, pesticide intensity, and humidity levels too can be monitored using different types of sensors as a part of NBIoT in agriculture. These resources can also be remotely controlled through the NBIoT. As the energy levels for these sensing operations are very low, the cost of this IoT based monitoring is very much economical for the farmers. On the other hand, the harvest can be maximized due to the efficient nutrition distribution to the plants. These initiatives are already being deployed in several countries and found to be very effective. Of course, it will be made even more efficient in the future.

NBIoT for Manufacturing

Manufacturing is an important economic sector for developing countries. Recently, manufacturing companies in the developing countries are experiencing extreme competition, mainly due to the increasing pressures from technological changes and global business challenges. Advanced manufacturing technologies strongly rely on various ICT technologies to achieve higher productivity, higher quality,

and lower production costs. However, the role of the Internet in manufacturing is still understudied. IoT is going to fill this void very fast. NBIoT is even more efficient to handle the issues of automation and energy efficiency in large manufacturing hubs (Routray & Sharmila, 2017). Thus, it is a hot choice for the industrial automation in the developing countries. In all these changing scenarios, overall efficiency and automation can be provided by NBIoT (Routray & Sharmila, 2017).

NBIoT for Healthcare

Healthcare provisioning in any country is one of the basic services. It is also a large sector due to the very nature of the services provided by this system. Healthcare system is multi-tiered and need proper collaboration among each of the tiers. In several healthcare processes, NBIoT can play a role of game changer. For instance, in emergency proceedings it can help the patients to get appropriate treatments while coming to the hospital from their residence. Using the sensors, the vital information of the patients can be sent to the doctor who in return can provide the appropriate support through the sensors till the patient reaches the hospital. Similarly, the telemedicine applications too can be improved through the NBIoT based sensor assistance.

NBIoT for Resource Management

Basic resources such as water, electricity, gas and other essential commodities are not properly managed in the developing countries. That leads to the poor resource utilization efficiency and loss of revenue for the government and associated public sectors. NBIoT based solutions already exist to improve the resource utilization efficiency in these areas. Smart metering and efficient resource distribution can be a game changer in these sectors. NBIoT based automation in the metering and resource distribution is quite cost effective and efficient. It can provide a real-time resource monitoring framework to the resource distributors. This is how the operators can directly monitor the efficiency of resource utilization. Thus, NBIoT is being deployed in several countries for the public resource management.

Extensions of NBIoT

NBIoT can be extended for several new services and applications. For instance, it can be extended for undersea and space applications. Undersea applications are measurement of ocean parameters such as pressure, temperature, salinity and tidal velocity; location finding and tracking of objects on the sea surface. Similarly, the marine environment of the sea surface can be monitored using NBIoT sensors. Satellite integration with NBIoT can provide a lot of new applications. Satellites (in fact, the satellite constellation) provide better coverage of services than the cellular networks. Reliability of satellite links is better than the cellular links and thus dependable for critical applications. Satellites with a well-managed constellation provide more than 99.9% availability which is much better than the cellular networks. In mission critical applications such as disaster management and real-time rescue operations satellite based IoTs are preferable over the cellular ones. More about these extensions have been presented in the following section.

Future Research Directions

NB-IoT is new in the cellular networks. However, due to its attractive features it becomes very popular in the LPWA regime. It was first standardized in LTE release 13 which was its first standardization for large scale deployment. In Release 14 several enhancements have been proposed for new applications. In the future there will be many more additions for its better function. The new directions considered for NB-IoT are: satellite NB-IoT integration for better coverage and wider reach; location determination; implementation of mission critical applications through NB-IoT; monitoring and measurement of physical parameters at difficult locations/ places. Satellite integration with NB-IoT will be a great advantage for its commercial applications. Cellular networks are not very much reliable all the time. The availability of the cellular networks these days is less than 99.9%. In the rural areas it is even lower. It can be enhanced to 99.99% or even better through the satellites (Routray & Hussein, 2018).

Location determination using NB-IoT is quite interesting. Location determination using the cellular networks has limited accuracy due to the sparse presence of the base stations. However, NB-IoT uses many sensors under each base station and it can provide much better accuracy than the cellular networks (Jiang et al., 2013). Due to the better accuracy in the locations, tracking too is very effective using NB-IoT (Ramnath et al., 2017). Location based services will be very much dependent on NB-IoT like infrastructure. These are the future value added services of NB-IoT and currently being researched. Location determination through the IoTs can be extended to both indoor and outdoor environments (Gu & Ren, 2015).

Disaster management and several other emergency services are very much dependent on the locations. For these services time is a critical resource due to its limitation. On the other hand these services must be provided at the right time with successful execution. Thus these services are known as mission critical applications. NB-IoT is a good choice for mission critical applications due to its widespread coverage. Satellite integrated NB-IoT can be very effective for these mission critical applications (Routray & Hussein, 2018).

There are several locations or places where human presence for monitoring and measurement are dangerous. Such cases can be handled through remotely placed sensors or sensor networks. NB-IoT is a low power and highly efficient sensor network. Therefore, NB-IoT is being researched for the deployment in such difficult places. For instance, ocean surfaces and floors needs to be monitored and its parameters such as the temperature, pressure and salinity needs to be measures regularly. This can be done through NB-IoT. For these applications, satellite coordination can be used. Even wired networks along with the NB-IoT sensors can execute these tasks efficiently. NB-IoT has enormous potential in the practical applications. Therefore, the future research directions associated with NB-IoT will have several ramifications.

CONCLUSION

In this article, the main advantages and attractive features of NB-IoT have been highlighted. NB-IoT is here to stay for a long time. It provides several advantages which are not found in other IoTs. It can be considered as a green IoT due to its energy efficiency and narrow bandwidth requirements. Main design related features of NB-IoT are borrowed from LTE. Thus the design methodologies of NB-IoT follow the LTE like framework. It is also true that NB-IoT is compatible with almost all types of the legacy networks of LTE. Its potentials are far reaching. NB-IoT is an LPWA technology that makes it more attractive over

other IoTs. This is especially important for the developing countries due to its economical deployment over other forms of IoTs.

KEY TERMS AND DEFINITIONS

Applications of NB-IoT: Uses of the NB-IoT technologies are diverse. Collectively it forms its applications. Several applications are available and new applications are emerging every year.

Energy Efficient IoT: Energy efficient IoTs reduce the consumption of energy to a large extent. These IoTs utilize the available energy optimally and can also harness it locally if appropriate arrangements are in place.

Green IoT: Energy efficient IoT is known as Green IoT. NB-IoT is an example of green IoT. These IoTs are in high demand because the battery life for these IoTs is more than 10 years.

Internet of Things: It is the extension of the internet through the interconnection of sensors/ sensing devices which can provide a lot of information about the environments where they are deployed. They can also activate or deactivate several operations through appropriate actuators.

Narrowband Internet of things (NB-IoT): NB-IoT is a specific type of IoT which uses a very small bandwidth and transmit power for its operations. It is a low power wide area network technology. It has been standardized in LTE Release 13 and 14.

NB-IoT Deployment: Placement of sensors, transceivers, actuators and other components of NB-IoT at the appropriate locations and the allocation of resources is collectively known as its deployment. Successful deployment is a challenging issue for any IoT.

INTRODUCTION

Internet of Things (IoT) focuses on the interconnectivity amongst people, sensors, actuators and processes. This term aims on the connection of various devices in order to provide data analytics and automation (Haseeb et al, 2017). An important requirement of IoT is ubiquitous connectivity and in order to achieve it, applications are needed for supporting the various sets of devices that will be used, as well as, communication protocols (Buyya & Vahid Dastjerdi, 2016). For instance, the aforementioned devices can be a smartwatch, a fitness band (Ranger, 2018), a television, a car and many more IoT related end user devices (Rouse, 2018). In addition, the IoT idea is also based on the concept of a digital home in which various daily devices (for example appliances) go online, are interconnected, and allow efficient data exchange among them.

Therefore, various sensing devices like Radio Frequency Identification Devices (RFID), scanners, GPS and so on are combined in order to form a wider network. The aim of that wider network is to have various devices connected and make possible the identification and management of them (Liu & Lu, 2012). Due to the variety of devices being connected together in order to allow data exchange, interoperability issues are encountered, which limit the applicability of IoT-related services due to the variety of IoT data protocols utilized by different sensors and data nodes. This article addresses the issues of IoT

DOI: 10.4018/978-1-7998-3479-3.ch064

interoperability and possible solutions in relation to it. Through the agility brought by virtualization, which allows gateway functions to be deployed on demand in an agile manner, this chapter discusses the concept of interoperability provision over heterogeneous IoT data protocols.

More specifically, this chapter discusses the problem of interoperability in IoT domains by introducing the most popular IoT data protocols that are commonly used today. Then, a proposed solution is described based on the agility offered by virtualized infrastructures with SDN/NFV capabilities. The basic functionalities of these technologies are briefly presented and finally a proposed approach towards the deployment on-demand of data protocol GWs is described.

BACKGROUND

During 1980s and 1990s, there was the concept of making objects smart, by integrating to them processing and connectivity capabilities, but it was slowed down due to the low progress in technological advancements (Ranger, 2018). Additionally, in the book “When Things Start to Think”, professor Neil Gershenfeld used the term “Things” which shows that there was an initial vision of Internet of Things (IoT) concept, back in 1999 (Rouse, 2018). The term IoT was coined by Kevin Ashton in a presentation regarding supply-chain management in 1999 (Kramp 2013). While he was part of the Auto-ID Center at MIT, he was involved in the Radio Frequency Identification Devices (RFID) applications extension in broader domains which is the basis of the Internet of Things (Buyya & Vahid Dastjerdi, 2016). Kevin Ashton with the term IoT wanted to describe a system that the real world is being connected using a ubiquitous network of sensors (Corcoran, 2016).

In order to fully understand the concept of IoT is better to consider the Internet, which is the basic infrastructure for interconnecting remote networking nodes, such as the IoT objects. The Internet origins are dated back to 1960s. TCP/IP was introduced in 1974 and by 1984 a thousand nodes were switched over to it for data transmission and as a networking protocol. In the 1990s and early 2000s, this connectivity trend continued, which gradually resulted in numerous connected terminals and devices. In present-day, people use smartphones in order to perform their daily tasks, mobile network allows for ubiquitous connectivity and the internet allows device connection from anywhere (Corcoran, 2016).

Nowadays, IoT applications have been found in different sectors, such as to systems which are industrial and closed-loop to commercial ones (Kolias, Stavrou, Voas, Bojanova & Kuhn, 2016). Examples of the devices are: cameras, lights, television, printers and so on. The number of devices which are currently connected to the internet is estimated to be around 5 billion and an increase is expected in 2020 to be around 25 billion. The future shows that IoT devices will be mainstream, increase technological advancements to areas such as healthcare by using monitoring wearables, to retail as well as transportation. There is a transition of the IoT devices and from monolithic boards are turning to modular devices so as to satisfy daily life's needs (Kolias, Stavrou, Voas, Bojanova & Kuhn, 2016).

IoT devices can use a variety of networks such as LAN, WAN, PAN or cellular networks. In addition, due to device restriction requirements such as battery, high autonomy and low cost, wireless technologies, such as RFID, Bluetooth, NFC are used (Díaz Zayas, García Pérez, Recio Pérez & Merino, 2017). RFID takes an important role in IoT. The RFID system includes back-end network applications and data acquisition. Devices as such even though they play an important role in IoT, still face various problems like standards compatibility. Moreover, besides RFID, wireless networks play an important role, allowing users to connect via various devices, creating the basis for the wider deployment of IoT systems (Liu & Lu, 2012).

IoT DATA PROTOCOLS

The devices, which are connected, have different protocols, which lead to interoperability issues (Blackstock & Lea, 2014) when they need to exchange data which are heterogeneous protocol-wise. Examples of protocols that are usually utilized by IoT sensors and devices as communication data protocols are the MQTT, CoAP, HTTP and UDP. These protocols are briefly described in the following sections.

MQ Telemetry Transport protocol (MQTT)

MQ Telemetry Transport (MQTT) is a lightweight messaging protocol, which is designed for constrained devices, networks which are not sufficiently reliable, namely utilizing low bandwidth with high latency (MQTT, 2014). According to Rouse (2018), it is a lightweight messaging protocol, since its messages consist of a fixed header which is 2 bytes, an optional variable header, a QoS (Quality of Service) level and a theoretically max message payload to 256Mb, but the max payload size supported by IoTF is 4Kb. MQTT's basic principles are to minimize the network bandwidth as well as the requirements of the device and ensure reliability and assurance of delivery. It is also ideal for machine to machine or IoT situations where various devices are connected as well as in cases where mobile applications are used and bandwidth and battery power are important. The term MQTT was coined in 1999 by Dr Andy Stanford-Clark from IBM and Arlen Nipper of Arcom (MQTT, 2014). MQTT has a diverse structure which can be a huge tree with no clear way to be able to divide it in smaller components that can be manageable. Therefore, this is a problem which in turn increases the complexity of the network. In addition, MQTT protocol has a problem with interoperability. A problem in terms of interoperability is due to the binary message payloads which contain no information of their encoding. Problems as such arise when applications from different manufacturers need to be connected and work together. Moreover, another problem is that the receiver is not able to know who the original message sender is. The only way to be able to know the sender is if it is mentioned in the message. The use of additional security features on top of the MQTT protocol causes a code increase which leads to difficulty handling the implementations (Rouse, 2018).

Constrained Application Protocol (CoAP)

Constrained Application Protocol (CoAP) is a web transfer protocol which is used with constrained nodes and networks. It is designed to be used with machine to machine applications like smart energy or building automation (Bormann, 2016). In specific, it is a specialized web transfer protocol for use with constrained nodes and constrained networks in the Internet of Things. The protocol is designed for machine-to-machine (M2M) applications such as smart energy and building automation.

In addition, CoAP allows devices like low power sensors and actuators to be able to communicate via the Internet. This protocol runs on devices which support UDP (or else User Datagram Protocol) and is ideally suited for devices which are of low memory and power as it offers small message size, lightweight messages and message management (Johnson, 2016).

This protocol, like the HTTP protocol, is based on the REST model which allows servers to make resources available under a URL. The clients can access those resources by using methods/commands like GET, POST, PUT and DELETE (Bormann, 2016). A description of the aforementioned methods can be found below (Shelby, Hartke & Bormann, 2014).

- GET: This method allows the retrieval of a representation in relation to information of the resources identified by the URI. Get is a safe method to be used.
- POST: This method refers to the processing of the enclosed representation. POST is neither a safe method nor an idempotent one.
- PUT: This method refers to the update or creation of resources identified by URI. PUT is neither a safe nor an idempotent method like POST.
- DELETE: This method allows the deletion of information identified by the URI. It is not safe a safe method but is idempotent.

The CoRE group has designed CoAP with the following features in mind:

- Overhead and parsing complexity.
- URI and content-type support.
- Support for the discovery of resources provided by known CoAP services.
- Simple subscription for a resource, and resulting push notifications.
- Simple caching based on max-age.

Hypertext Transfer Protocol (HTTP)

Hypertext Transfer Protocol (HTTP) is a network protocol that web browsers and servers use in order to communicate. The HTTP can be easily recognized in a web browser by looking at the URL as it has the signature of http in the beginning. This protocol is similar to other protocols like FTP (File Transfer Protocol) as it uses a program in order to request files from a server remotely. In the case of HTTP, the program that is used to request files is a web browser and requests HTML files which are displayed in the format of text, images, hyperlinks and so on. In addition, this protocol unlike other protocols is stateless, which refers to the ability that it has to stop the connection once a request has been made and executed. This protocol has been created by Tim Berners- Lee in the early 1990s (Mitchell, 2018).

HTTP offers three message types which are GET, POST and HEAD. The GET type refers to messages which are sent to a server and contain only a URL. The URL can have zero or more data parameters which can be added at the end of it (Mitchell, 2018).

The POST type refers to any additional data parameter which is placed in the body of the message and not in the end of the URL (as it happens in the case of the GET type). The HEAD type is similar to GET but instead of replying with full URL information, the server sends back only information in regards to the header (Mitchell, 2018).

As with the other protocols, the HTTP has its issues. Some of the issues in relation to this protocol relate to message transmission failure due to different reasons like:

- User error
- A problem with the web server or browser
- An error that exists in the web pages creation and
- Temporary problems in regards to the network

In case of an issue, the protocol captures the problem of failure and then reports an error code in order to point out what kind of error it is (Mitchell, 2018).

User Datagram Protocol (UDP)

User Datagram Protocol (UDP) is a transport layer protocol and is used with the IP network layer protocol. UDP is written by John Postel and defined by the RFC 768 and provides a datagram service to an end system (Fairhurst, 2008). The issue with this protocol is that it provides an unreliable service meaning that there is no guarantee that the message will be delivered and protected from duplication. It is an unreliable, minimal, message passing transport to applications as well as upper layer protocols. It offers an efficient communication transport but it does not have reliability or congestion control. Due to its unreliability, application designers often consider it as a transport. In cases of data duplication, the designers need to verify that the application can handle duplication and implement appropriate mechanisms in order to detect it. Moreover, this protocol has security issues. In cases of applications that have sensitive data, a separate security service needs to be provided in order to use additional protocol mechanisms (Fairhurst, 2008).

IoT ARCHITECTURE COUPLED WITH CLOUD COMPUTING SYSTEM

The architecture of a modern IoT system today is usually coupled with cloud computing systems, including both central and edge nodes, providing increased scalability and performance, as well as third party access to the IoT infrastructure. The first layer consists of sensors and actuators. The second layer (Internet Gateway) involves sensor data aggregation systems and a conversion of analog to digital data. The third layer (Edge IT and Fog computing systems) consists of IT systems which preprocess data prior to its transfer to a data center or a cloud. The last layer (Data Center/Cloud), layer four, is the stage where data can be analyzed, managed and stored. Below follows a description of each of these IoT stages.

Figure 1. Architectural Layers of a modern IoT system

Figure 1 depicts the four layers of an IoT architecture couple with cloud computing resources, which are briefly described hereby:

- **Sensors and Actuators:** The sensors have the ability to collect data from the environment and provide useful data. A different name of a sensor is transducer which is a physical device that is used so as to convert one energy form to another one. An example of a sensor is a microphone that can take the sound waves and convert them into electrical energy. (Eller, 2017)

A transducer that can be found in different IoT systems is an actuator, which means that it operates in an opposite direction of a sensor. An actuator takes the electrical input and converts it to a physical (Eller, 2017). Examples of an actuator's process are: to shut off the power supply, to adjust the air flow valve and so on. The first stage of sensors/actuators involves different devices such as accelerometers, air sensors, heart rate monitors and so on (Fuller, 2018)

- **The Internet Gateway Layer:** Data from sensors need to be aggregated to one node for further processing. Ccssioanlly and depending on the node type, the data may need to change before it enters the processing stage. Moreover, data need to change from its analog form to a digital one and the Internet Gateway Layer assists in achieving this. Sensors/Actuators and the Internet Gateway Layer can be found close to each other and therefore, that is helpful in order to achieve real time pre-processing. Moreover, the internet gateways can be built and support analytics, malware protection and data management (Aher, 2018). A gateway is an edge device, it is located externally to the data center and it is important to know its location. Additionally, gateway devices can be found in various environments like factory floor to mobile field stations and they are built in order to be portable, durable to temperature changes, vibration and deployable (Fuller, 2018).
- **Edge IT and Fog Computing:** This is the third stage of the IoT architecture. In this stage, data enter in the IT systems so as to be further analyzed. This layer (Edge IT) is located in remote offices or in edge locations comparing to the two aforementioned layers (Sensors/Actuators and the Internet Gateway Layer) which are located close to each other. The IoT data can be huge in size thus taking a big amount of network bandwidth and due to this reason, the edge systems via analytics allow data to be minimized in terms of its amount (Aher, 2018). In addition, while processing the data different issues can be encountered such as security issues, storage issues and data delay. By following a staged approach, the data can be preprocessed, meaningful results can be generated and only those will be passed on (Fuller, 2018).
- **Data Center/Cloud:** This is the fourth and last stage of the IoT architecture. Data can be forwarded to cloud-based systems or a physical data center when they need to be further processed. In this way, data will be analyzed, managed and stored by powerful IT systems (Fuller, 2018). Moreover, by exploiting the virtualization capabilities that cloud systems offer, additional functions may be also considered in the processing process in order to perform additional tasks, such as big data analytics or business intelligence tasks.

The generic architecture of IoT systems consists of systems which are complex and perform various tasks such as collecting information in relation to people, environment, psychological measurements, tracking things and so on. Information as such is stored in IoT back end with or without the aid of a gateway (Haseeb, Hashim, Khalifa, Ismail, 2017). A gateway stores, translates and forwards data to an IoT back-end system. There are also gateways which are more complex and allow the proprietary device

management of IoT devices. In addition, there are IoT gateways which allow process automation prior to forwarding the processed data to a back- end cloud for storage and additional processing. The IoT back-end has a limit of the capabilities of a physical IoT device and does not have a mechanism in order to overcome this issue. (Haseeb, Hashim, Khalifa, Ismail, 2017). The coupling of traditional IoT systems with cloud computing and virtualization infrastructure can contribute to overcome the aforementioned limitations by adding functions in an agile manner that are able to perform tasks on demand. Among the various functions, one of the main challenges that the modern gateways have to face is the interoperability provision over the various data protocols that the IoT sensors and nodes use.

IoT INTEROPERABILITY: VERTICAL AND HORIZONTAL DEPLOYMENTS

An important requirement of IoT is interoperability as the “things” which are connected to the Internet need also to be found, accessed and managed in a unified way. Therefore, interoperability plays an important role in this case and is a feature that it should be appropriately supported by the IoT Gateway.

In an IoT architecture, the devices need to interoperate and communicate with a gateway which is cloud based. This though is not always true due to the various devices which are connected, many communication protocols which are used as well as many application layer interfaces. Thus, this diversity of devices leads to vertical solutions which are isolated. These vertical solutions don't allow systems to communicate in order to exchange valuable information and therefore do not follow the true nature of IoT (Haseeb, Hashim, Khalifa, Ismail, 2017).

Figure 2. Vertical IoT approach

Figure 2 depicts a graphic of the vertical isolated approach. Vertical solutions have dominated the IoT devices and systems. A company using a vertical model can control an IoT device, a gateway, an application and also a cloudbased service. Additionally, there is a clear control in terms of decision making from the entry stages and also the users deal with one provider in cases of technical difficulties.

The vertical solutions have more drawbacks than benefits, specifically in terms of user perspective. An example is that there may be different companies offering different solutions to a building (one company can focus on remote control on electric light usage and the other on the security system's IoT sensor) thus this is impossible to control the devices using a single application as each of the companies use their own platform (IoT, 2018). In addition, it is in a virtual manner impossible to be able to manage a diverse set of IoT devices (Haseeb, Hashim, Khalifa, Ismail, 2017).

Figure 3. Horizontal IoT approach

Besides the vertical solution, there is the horizontal approach. Figure 3 shows an example of an horizontal solution. A horizontal platform is used so as to streamline the user control of IoT devices. In the horizontal approach, there is a platform which allows various companies to be able to develop applications, IoT devices, which are compatible and also to interact amongst each other using a common framework. Furthermore, this approach is an ideal choice for enterprises while it offers ease of use, application development. The horizontal solution reduces system costs and increases the data monetization opportunities (IoT, 2018).

IoT INTEROPERABILITY PROVISION BASED ON VIRTUALIZED INFRASTRUCTURE

IoT offers interconnectivity amongst diverse devices but this comes with a price as there is a lack of interoperability. Due to the reason that the companies offer solutions independently of each other, have different platforms and frameworks, there is a problem with integration with one another (Eastwood, 2017). In order to overcome the interoperability issue, a solution is by using virtualization and software-defined techniques. There are two technologies which promise a cost effective scale and versatility,

which is necessary for IoT, namely the Software Defined Networking (SDN) and Network Functions Virtualization (NFV) (Bizanis, Kuipers, 2016).

Software Defined Network

SDN started on campus while researchers were experimenting with new protocols. The result was to come up with an idea of making network devices programmable and allowing them to be controlled by a central element. In addition, SDN allows: i) The separation of control and forwarding function, ii) Control centralization, and iii) Has the ability to program the network's behavior with the use of well-defined interfaces (Pate, 2013).

In SDN, the IoT elements are devices which have no intelligence in order to control as well as forward data traffic. This technology acts as the brain of an entire network and resides on multiple servers in a cloud network. Additionally, the entire network management and the control of operations are called the SDN controller. SDN controls the network and reduces the burden of network operators as it aims on avoiding network configuration errors which is an issue very common today (Alenezi, Almustafa, Meerja, 2018).

Network Functions Virtualization

Network Functions Virtualization (NFV) was created by a service providers' consortium. The service providers tried to speed up the network services so as to increase revenue and growth plans and found that hardware-based appliances had a limit in order to achieve that. So, NFV was a solution in order to accelerate service innovation and provisioning (Pate, 2013). In NFV, there is a software manager similar to SDN in order to allocate and release resources. In addition, NFV devices can be controlled by using a central SDN controller thus making it easier for SDN and NFV to coexist and function together. The NFV architecture is composed of three components: Physical Hardware, Virtual Hypervisor Layer and Virtual Machine (Alenezi, Almustafa, Meerja, 2018). The Virtual Hypervisor Layer runs on hardware and manages resources like the power of CPU, memory and storage capacity. The Virtual Machine refers to software, which has the ability to emulate the architecture and functionalities of the physical platform by using hardware resources. A physical hardware is able to host more than one virtual machines. (Alenezi, Almustafa, Meerja, 2018). NFV has been a popular choice amongst telecommunication companies or else Telcos as they are suffering from interoperability issues. NFV aimed at aiding on operational challenges, high costs, device heterogeneity and proprietary appliances. Issues regarding heterogeneous devices are the following (Haseeb, Hashim, Khalifa, Ismail, 2017):

- 1) Fixed configuration: The Telco hardware has a fixed IP which does not change for a long period of time
- 2) Manual Management: The management and configuration of telco equipment requires moving physical staff and this can be achieved once at a time.
- 3) Rapid growth of IP end points: Many users are able to access the Internet thus this makes it difficult if a central provisioning is not established.
- 4) Network endpoint mobility: Due to the fixed nature of networks, the requirements for mobility take a longer time so as to reconfigure the network in regards to different scenarios.
- 5) Elasticity: Due to the reason that there is no mechanism in order to upgrade or even downgrade physical software, the networks need to be over provisioned.

Software Defined Network and Network Functions Virtualization

These two technologies are quite different but they share common principles. The WAN or else Wide Area Network is an environment which is closed and static and even though improvements in regards to automatic capabilities have been made, there is still a manual process in terms of general management and delivery. The use of SDN and NFV allows the networks to be driven by centralized software control capabilities which are able to program an entire network using a set of open APIs. Virtualization is also beneficial as the costs of deploying services around the network minimize (Vodafone, 2016). NFV is driven by dynamic requirements and is associated with the evolution of cloud. Nowadays, there is an evolution in terms of delivery service thus virtual technologies offer the same services as physical ones and they are also instantiated when they are needed. NFV offers a dynamic set of capabilities and requires a dynamic network in order to connect them. SDN takes many forms like in the example of SD-WAN which targets an enterprise WAN. A challenge of SDN is that the network is controlled using open APIs without affecting the physical underlying connectivity. A customer will be able to see development in terms of self service capabilities which are not easily available in the current day in terms of WAN and security services. In addition, another positive aspect is to provide real-time visibility in terms of transport and application performance across the network. In order to decide whether to deploy SDN or not, an organization needs to understand several aspects such as the sites connected to the network, the application flows and the data type that these sites will traverse. When the previous aspects have been decided and understood, then it will be easier for the business to consider the dynamicity of its services, the criticality of data and the internet transport that the content needs to consume (Vodafone, 2016).

Furthermore, the use of these technologies (SDN and NFV) aims to face the 5G interoperability challenge by allowing the automatic deployment and programming of network services. These technologies are cost effective and provide the necessary versatility for the IoT services. Additionally, the 5G networks need to support software network technologies and the SDN and NFV are important as they are an ideal choice. As mentioned previously the SDN aims at basic connectivity services whereas the NFV provides orchestration, a virtualization framework and aims at a larger scope. In order to be able to implement these technologies a virtual gateway is needed as it ensures the interoperability amongst objects and technologies. Furthermore, additional KPIs metrics need to be evaluated in order to ensure the quality of QoS and QoE which is perceived by the end user. The IoT platform needs to be consisted of physical and virtual parts and be on top of a testbed so that the protocols MQTT, CoAP UDP will be instantiated and set up in order to provide an interoperable layer by using a virtual gateway.

The virtual gateway's aim is to provide the interoperability of IoT NFVs in different domains so as to unify the various and diverse smart objects which operate by using different IoT protocols. The ideal choice of protocols is MQTT and CoAP as they are open standards and they provide a more suitable solution to constrained environments in regards to HTTP.

In specific (see Fig. 4), the project envisages the testing/deployment of specific VNFs, which are mapping functions (i.e. proxies) of popular IoT data protocols (such as MQTT and CoAP) to generic data protocol (such as UDP or HTTP) in order to provide a common interoperable layer over the heterogeneous IoT nodes deployed at heterogeneous IoT domains and testbeds.

Figure 4. SDN/NFV-driven IoT interoperability on top of a virtual-based GW

FUTURE RESEARCH DIRECTIONS

The VNF formulation of the software-based IoT mapping functions can facilitate further the SaaS business model of them, while the integration of SDN rules in the virtualization environment can further upgrade the provision of the interoperable services following the SaaS/PaaS model. A major factor towards this in the future is the provision and support of slicing, which will support that service isolation can be achieved and therefore multi-tenancy exploitation of the infrastructure.

CONCLUSION

Internet of Things aims at the interconnectivity between people, sensors, actuators and processes. Moreover, diverse devices from various vendors are being used and connected in order to provide data analytics and automation. IoT allows everyday objects to act like “smart” and being connected to the internet and allow the users to perform various tasks. Examples of IoT can be a smartwatch, a fridge, a car and so on. Due to the vast majority and diversity of devices which are being connected and share information, as well as the different protocols each of them uses, a problem of interoperability is being defined. This interoperability issue can be solved by using virtualization technologies such as SDN and NFV. These virtualization techniques allow the minimization of costs that existed in physical devices, share same services as the physical ones but they are instantiated when they are needed. In order to use these technologies at their best possible way, it is important to consider several aspects before proceeding on choosing them such as the sites that will be connected to the network, the application flows and the data type that these sites will traverse. Furthermore, the combination of SDN and NFV aims to face the interoperability challenge as these technologies are cost effective and provide versatility for the IoT services. In order to implement these technologies, a virtual gateway is needed so as to achieve the interoperability between the objects and technologies. The IoT platform consists of physical and virtual parts and is on top of a testbed so that the protocols MQTT, CoAP and UDP will be instantiated.

KEY TERMS AND DEFINITIONS

IoT: Internet of things. The interconnection via the internet of computing devices embedded in everyday objects, enabling them to send and receive data.

IoT Interoperability: The ability for IoT systems or components of systems to communicate with each other, regardless of their manufacturer, technical specifications, or data protocols.

IoT Protocols: A standard set of rules that allow IoT devices to communicate with each other. These rules include what type of data may be transmitted, what commands are used to send and receive data, and how IoT data transfers are confirmed.

Network Virtualization: Abstracting network resources traditionally delivered in hardware to software. It can combine multiple physical networks to one virtual, software-based network, or it can divide one physical network into separate, independent virtual networks.

NFV: Network function virtualization. Network architecture concept that uses the technologies of IT virtualization to virtualize entire classes of network node functions into building blocks that may connect, or chain together, for creating/providing communication services

SDN: Software-defined networking. SDN architecture aims to make networks agile and flexible. Dynamic, programmatically efficient network configuration in order to improve network performance and monitoring making it more like cloud computing than traditional network management.

Network Science for Communication Engineering

INTRODUCTION

Network science is associated with the study, analysis, modeling and applications of networks. Networks are not limited to any one or two disciplines. Rather, networks are found in almost every field in different forms. For instance, in electrical engineering we have electrical circuits which are known as networks. In communication engineering, we have communication networks of different types such as access networks, regional networks, core networks and the Internet. Computer networks are very much identical to the communication networks these days. In fact, unification of communication and computing has given birth to the Internet. Power distribution networks are found throughout the world. They are huge in size and directly affect the human activities across the world these days. In our society, we have different types of social networks. Social networks through the communication platforms have given birth to the online social networks such as LinkedIn and Facebook. However, the social networks are very much older than the current social networks found online. The social networks were started along with the civilizations. However, their studies in psychology were started much later in the twentieth century (Moreno, 1934). Transportation networks are formed through the roads connecting cities, towns and villages. These transportation networks are also found over the water and air as the shipping and airline networks. Based on the economic activities between different countries and regions, trade and economic networks are formed.

In the nature, many different types of networks are found in various forms. Human brain is a complex network of neurons. In the human body there are some other networks as well such as blood circulation network and the lymphatic networks. In genetics, we can find out the link between generations and different clans. It is also a complex network. Based on the genetics, doctors classify different diseases and utilize them for advanced research and clinical treatments. This branch of medicine is commonly known as network medicine. Metabolism of organisms follows different sequences of processes which forms a metabolic network. Rivers and streams form natural water supply networks. In the modern world, there are several resource supply and distribution networks. Structural networks are found in different mechanical designs and civil architectures. In scientific collaborations we find the citation networks.

Complex systems are the large and randomly related with their components. The components of these systems are complexly related with each other. In other words, these systems are made up of many heterogeneous and non-identical elements connected through several diverse interactions. In every complexity, we always find a network is associated (Albert & Barabási, 2002). In order to understand the complexities, the underlying networks have to be understood properly. As we have seen above, every discipline has complex issues. Mapping the complexities accurately we can find a network which has the potential to simplify its understanding (Albert & Barabási, 2002). This is the main reason behind the popularity of network science.

DOI: 10.4018/978-1-7998-3479-3.ch065

Network Science: Origin and Background

Network science is being treated as the study of networks using different scientific methods. Its popularity and widespread applications are very much recent. However, the discipline has been developed quite clandestinely since a long time. The exact beginning of network related study is not known. Regular networks were being studied in geometry in several old civilizations. These principles were also being used in the building and structural architectures. However, graph theory which is considered as the mathematical basis of networks was started by Euler in 1735. His visit to Königsberg was the key in the development of graph theory (Alexanderson, 2006). The famous “Seven Bridges of Königsberg” puzzle was solved by Euler and it was the foundation of graph theory. Since then, graph theory became a systematic branch of mathematics. The first application of graph theory in engineering was found in the study and analysis of electrical networks in circuit theory. Early applications of network science are recorded in Psychology (Travers & Milgram, 1967) in which the psychologists tried to explain the social behavior of people. In the 1930s Moreno used the principles of networks to analyze the social networks (Moreno, 1934). The mathematical models for the networks other than the graph theory came quite late in the late 1950s. The mathematical model for the random networks was developed by Erdős and Renyi in 1959 (Erdős & Rényi, 1960). This was the first model to analyze the real networks. Their formulation assumed that every real network is random in nature as their nodal degrees follow Poisson’s distribution. In the late 1960s and early 1970s, communication networks were studied rigorously as their size and applications got expanded. The Granovetter network model was developed in 1973 which was very much fundamental like the random network model developed by Erdős and Renyi (Granovetter, 1977). Ecological networks and several biological networks were brought in to the picture in the late 1970s. After these practical applications, network science attracted researchers from almost every field. Two papers by the network scientists in the late 1990s opened the floodgate of research in this discipline. They are: the paper of Albert and Barabási (Albert & Barabási, 1999) in *Science*, on the scaling of the Internet published in 1999; and the paper of Watts and Strogatz (Watts & Strogatz, 1998) in *Nature*, regarding the small world networks published in 1998. These two papers showed the essence of network science in the modern scientific and technological analysis.

Since the publications of those two ground breaking papers in the late 1990s, network science became considered as a fundamental discipline in the study of networks and their applications to understand the natural complexities. Complex systems such as the Internet and human brain are built over large networks. In order to understand their principles, it is essential to understand their underlying network. Several branches of science, arts, and commerce now use network science as one of their main tools to analyze the complexities. For instance, in physics, chemistry, biology, communication engineering, material science, psychology, medicine, economics, and political science network science is used as a tool to explain the underlying complexities. In communication engineering, network science is used to study the dynamics and stability of the networks (Routray et al., 2015). The use of statistical modeling in the analysis of optical networks is found in Waxman (1988) in which the nodal degrees of the core networks were found to follow Poisson’s distribution. A complete statistical formalism for the fast estimation of optical network parameters was developed in Korotky (2004). A similar fast estimation of mesh optical networks was developed in Labourdette et al. (2005). Optical network topologies can be developed using the statistical principles of the optical networks (Pavan et al., 2010). Following the successes of these models several statistical models for different parameters of core and access networks have been developed in the recent years (Routray et al., 2015). Network economics can also be analyzed using network science approaches (Routray et al., 2017). The social networks are really complex and

their characteristics can only be understood when they are analyzed using mathematical models developed in network science.

Characteristics of Network Science

Now, network science has been established as a new branch of science which uses several scientific methods to analyze complex networks and complexities. It is an interdisciplinary field of study of networks to address the problems associated with large networks (Albert & Barabási, 2002). This field is very much empirical and data driven. It is founded on the logical bases of several mathematical concepts such as graph theory, probability, statistics and linear algebra (Goldenberg et al., 2010). It is also quantitative in nature because its parameters can be quantified. However, the estimations are very complex if the size of the network is large. Therefore, it needs computational tools for fast and accurate analysis of its parameters. Overall, it is a logical discipline which has the potential to resolve the complicated problems across many fields.

The main principles and applications of network science as observed in the recent times are: the applications of mathematics, in particular statistics and probability, to analyze the underlying concepts; to analyze the dynamics of the networks with the changing conditions; and to generate and design the networks found in the nature. The study of network science was started as the analysis of social interactions in the society (Moreno, 1934). In the 1950s, mathematicians developed analytical models to study the exact behaviors of the networks (Erdős & Rényi, 1960). In this work, the networks were considered as random and the nodal degree distributions normally follow Poisson's distribution. However, later it was found that this assumption of random behaviors of all real network nodal degrees was wrong. In Albert and Barabasi (1999), and Watts and Strogatz (1998), the new concepts of real complex networks came into light. Since then, network science has been systematized in a very scientific way. Some complex networks have been developed in the recent years such as the online social networks, huge trade networks based on the logistics, and the communication networks which is a complex hybrid of many different types of components. Newman et al. (2002) provided the basic framework for the analysis of social networks. Nekovee et al. (2007) and Borgatti et al. (2009) have developed the concepts for social network analysis and the anomalies in the behavior can point out the critical properties of the social networks. Applications of network science have spread in to several new areas which were very much uncharted before two decades. Network medicine is one such area in which the principles of network science are applied to medicine to find out complex relationships between the diseases (Barabási et al., 2011). Many such applications are emerging in almost all areas of science, arts, and commerce.

Network Science in Engineering

There are several complexities in engineering. However, there is no suitable tool to understand and analyze those complexities. In order to understand the complexities and to solve the problems linked with them, engineers have to first analyze and comprehend the associated networks. Many engineering systems are very much random and stochastic in nature. The randomness can only be properly understood through the statistics. Network science uses several powerful statistical tools (Fienberg, 2012). Therefore it is good at the analysis of real world complex problems. Similarly, complex system modeling, analysis and design need the principles of network science for simplification. Network science correlates many diverse fields in a very elegant way. It is now applicable to fields where mathematics had no previous scope. Most of the evolving networks are complex and need advanced tools for their analysis. Complexities

in the networks can be properly modeled through network science. Artificial intelligence can be well complemented through network science in the complex problems. Network science has a great potential to analyze the complex problems of engineering across several disciplines.

Network science is a natural tool for the solutions of the complex engineering problems. For instance, the Internet was developed in the 1970s, but became popular only after the arrival of World Wide Web (WWW), because the network dynamics of a large globally connected network was not known. That is the reason why many engineers and scientists have a lot of doubts on the stability and sustainability of the Internet. Through the WWW framework, the Internet was expanded very fast. It provided both commercial and non-commercial services around the world. Several new economical and philanthropic activities were started through the Internet. However, its principles and statistical mechanism were understood much later in Albert & Barabási (2002). Similarly, the failures in the power systems are quite complex. Mainly the faults like the cascade failure are very much catastrophic for the power systems. Several such failures have taken place in the past in many countries. However, the solutions to those failures were not available to the engineers. That is mainly to understand the power failures in the transmission networks they had to understand the networks first. In fact, there was no such tool to analyze the huge power networks. In contrast, now network science provides proper framework to analyze the power networks (Buldyrev et al., 2010). Similarly, the inland transportations across the world are carried out through the road networks. These networks in large countries are too big for the engineers to analyze them when something like optimization or renovation is required. Using network science based solutions it can be simplified. The global trade networks are really huge. They cannot be studied accurately without network science.

In the above examples, we observed that the complex problems of the modern world is too complicated and needs smart solutions. In order to understand the problems, the engineers need to understand their underlying complexities. We have seen that these problems can be understood using network science. This is how network science has evolved as a natural solution for complex engineering problems in the recent years. In the long term, network science is going to be an integral part of modern engineering to deal with the complex problems.

Network Science in Communication Engineering

Communication engineering is associated with large communication networks. Therefore, it is associated with network science by default. Communication networks are made up of nodes and links. Nodes are the information hubs of networks. They provide basic signal processing and their conditioning for further utilization elsewhere in the network. The links basically carry the signal from one node to the other. The links can be wireless or wired. Almost all the core networks are wired. However, a large part of the access network is wireless. That is due to the popular service provisioning through the mobile networks, WiFi, WiMAX and several other wireless technologies. Both the node and link related parameters of communication networks can be analyzed using network science.

Statistical analysis and modeling of networks is now an integral part of network science and engineering (Fienberg, 2012). In case of communication networks, it can be used for the planning and dimensioning. In communication engineering, engineers focus on the analysis and modeling of both node and link parameters for network planning, dimensioning, cost estimations, design, overhauling, renovation and expansion. Node parameter analysis normally provides the network dynamics and the nature of the networks. Link length parameters of the networks provide the cost associated with the links. In the planning and design stage, the estimations are to be done with partial information because the complete

information is not available (Routray et. al., 2013). These are challenging problems and the estimations have to be accurate and trustworthy. In these early stages of planning, network science based statistical models can be used to estimate the parameters of network economics (Routray et. al., 2017). Estimation of link related parameters of communication networks using the statistical models obtained from the network science is popular and trustworthy (Routray et. al., 2014).

Main motivation for network science in communication engineering comes from its abilities to analyse the networks and its characteristics. Statistical analysis and modeling of the network parameters are essential components of network science and engineering. They provide several critical behavioural aspects of the networks (Korotky, 2004). Network dynamics cannot be understood without the statistical analysis. In communication engineering they are helpful in the estimation of network parameters and characteristics (Korotky, 2004). Network classification and characterization are very much simpler through network science. Even, the network stability and traffic engineering aspects can be analyzed using the statistical analysis of communication networks (Korotky, 2004). Quick estimation of network requirements which is required during the faults and network overhaul can be performed with good accuracy using the statistical models (Korotky, 2004; Labourdette et. al., 2005).

Node Modeling

Nodes are the meeting points of the links. The central nodes have a lot of connections or high nodal degrees (nodal degree of a node is the number of links connected to that node). Nodal degrees of networks can be used for their characterization. Based on the distributions of the nodal degrees networks can be random or scale-free. Similarly, when a network provides easily accessible paths between any node pairs, it is called a small-world network. In the following paragraphs these networks are described briefly.

Random Networks

Random networks are those whose nodal degree distribution follows the Poisson's distribution. It is well known that Poisson's distribution has only one parameter for its presentation. This parameter is also the average value of the distribution. When the average value becomes large, the probability distribution function (PDF) of this distribution takes a bell shape (it is also known as the bell curve) which is similar to the PDF of the normal distribution. Random networks are not very well connected (Routray et. al., 2015a). Initially the Internet was thought to be a random network due to its sparse and irregular connections. However, later measurements confirmed that the Internet is not a random network. In the early days such as 1970s and 1980s, the core optical networks used to be random to a large extent (Waxman, 1988; Pavan et. al., 2010). However, from the recent analysis of the core networks, it is found that now they are shifting towards scale-free nature (Routray et. al., 2015a).

Scale-Free Networks

Scale-free networks are very much different from the random networks. Their nodal degrees follow hyperbolic shapes or the power-law distributions (Adamic & Huberman, 2000; Routray et. al., 2015a). Typically, the distributions of the nodal degrees of these networks have shape similar to that of rectangular hyperbolas (Routray et. al., 2015a). There are several scale free networks found in the real world. The Internet is found to be a scale-free network. These scale-free networks exhibit some specific kind of dynamics and very much stable. The Internet too exhibits these characteristics.

Small World Networks

In these networks, the number of hops or links between any two nodes does not exceed a specific threshold. Typically the number of hops (or links) required between any two randomly chosen nodes varies proportionally with the logarithm of the number of nodes N in the network (Routray et. al., 2015a). Therefore, a distant node in the network can be reached by traveling through a very few number of hops or links. Social networks and the neural networks of the brain are typical small world networks. However, these characteristics are also exhibited in some communication networks.

Link Modeling

Links of the networks are the carriers from one node to the other. Sparse networks have very few links than the maximum possible links. However, the core networks are not sparse. Rather we find more links in core networks. Highly demanded core networks may be well connected as a full mesh network. More than the connectivity, the links play bigger roles in determining the survivability of the networks. If a node is connected with the network through just a single link then the failure of the link will stop the services to that node. Lengths of the links are directly associated with their cost parameters. Using the link lengths we can quantify the capital expenditure (CAPEX) of the links. Link parameters or elements such as the repeaters, amplifiers, performance monitors and several other sensors are directly related with the link lengths. These parameters and their numbers can be estimated from the link lengths. If a network is too large or the link lengths are not known then the statistical models of the link lengths can be used (Routray et al., 2015). One such model has been developed for the core networks which can be found in Routray et al. (2013). The link statistical model developed in (Routray et al., 2015) provides the statistical model for link lengths which can be estimated from the very basic information of the network. It needs just the coverage area and the number of nodes of the network. Knowledge of these two parameters will not only provide the statistical model for link lengths but also provides the details of the components required along the links. These estimations are very much realistic and can be used for network dimensioning. Link related CAPEX and OPEX too can be estimated using this model.

In (Routray et. al., 2013), it is shown that the statistical model for link lengths of the core networks follow general extreme value (GEV) distribution. The parameters of the GEV distribution are estimated from the coverage area and the number of nodes of the network. The associated input parameters of the statistical model such as the coverage area can be found from the network node locations (Routray et. al., 2014a). The developed GEV model is used for the estimation of the link length dependent parameters in core networks (Routray et. al., 2014).

Other Models in Communication Networks

Besides the nodes and links, there are several other parameters in communication networks which play critical roles in its operations. Therefore, the statistical models for the other parameters of communication networks are required and it is possible to develop them. In addition to the link lengths, there are several other length parameters which are used for practical communication engineering. Traditionally, the shortest path lengths are used for traffic routing and minimization of energy consumption in the transmission. However, in the modern networks we also need the statistical models for the minimum hop path lengths. These minimum hop paths may not be the shortest paths, but they encounter the least number of nodes along their journey. Nodes are the main processing points along the communication paths. So, more

number of nodes along a path means the time spent in the intermediate processing is longer. Therefore, the delay in the transmission is proportionately longer. Minimum hop paths provide the guarantee that the nodal processing delays are at their minimum level. Similarly, backup path lengths are required in case of a node or link failure. Restoration of the services along the alternative routes needs the backup paths. In the modern world where 99.999% reliability in service provisioning is the lower threshold these statistical models provide a lot of advantages in traffic planning and resource optimization.

The shortest path lengths for the core communication networks are found follow Johnson S_B distribution (Routray et. al., 2015). The four parameters of this distribution can be estimated from the coverage area and the number of nodes of the network. This model can be applied for the practical estimations of shortest path dependent parameters. The lower bound of energy consumption in transmission can also be estimated using this model.

FUTURE RESEARCH DIRECTIONS

Network science has a very bright future as it is the main tool to analyze the complex systems. There are many complex systems found in the real world. Network science is used in their studies and provides proper analysis. In medicine, it has been found that several diseases are genetic and thus are transferred from one generation to the other genetically. This is a complex field to analyze the genetic links from one generation to the other. However, network science is able to analyze them quite smoothly. This branch of medicine is known as network medicine as the genetic links are established using a network based model (Barabási et al., 2011). Based on the studies of network medicine, a human disease has been developed which can show the potential transferable diseases from one generation to the next. It also shows the links between the group of similar diseases. In the future, this study of network medicine will be further improved. In fact, all the diseases can be explained using some kind of network based models. Thus, network medicine is regarded as one of the main tools for precision health studies. It looks very clear that it will be very popular in the future.

Similarly, the power grids are being interconnected for better management of power generation, and distribution. Even the smart grid initiatives are being considered for better energy efficiency. The interconnections of grids make them very complex and difficult to manage. Now, several network science based methods are being used to study these huge grids. In fact, the nature and dynamics of these grids are not formulated according to the principles of network science. Now, network science is being applied to analyze the power grids. Hopefully, the future failures of the power grids can be prevented using the power system dynamics of the grids.

With the arrival of the new mobile generations and the Internet of things (IoT), the human living environment will be very much networked. IoT and its pervasive applications would make the whole world a very complex network. In order to understand the IoT properly, network science is required. Its effective design, energy efficiency, monitoring and all operational aspects can be analyzed using network science. IoT and the upcoming new mobile generations can have several good and bad effects on the human lives. Therefore, the mobile networks, IoTs and their other supporting networks must be studied carefully. This is clearly a future application network science.

Chaos is considered as a natural phenomenon of the universe. It is found in every corner of the universe at different scales such as in the femto, nano, and micro scales in the materials, and also at a macro scale covering a large portion of the universe. For instance, the movement of the galactic clusters and their constituents show several chaotic behaviors. Similarly, the motion of the micro, and nano-particles too

show a lot of random and chaotic characteristics. These chaotic behaviors can be analyzed accurately through network science. This is also a future application network science. Like network science, artificial intelligence is also a powerful tool to analyze the system behavior. Even both the fields use the behavioral statistics to a large extent. Thus the conjugation of network science and artificial intelligence looks like a natural choice. In fact, these two tools can analyze the complexities better than any other. So, in the future, network science can be a natural companion of artificial intelligence and machine learning in the complex system analysis.

CONCLUSION

Network science is an elegant field of study and analysis of complex systems. Complexities cannot be analyzed properly without network science. It is an interdisciplinary field of science which interconnects many different fields. It provides several creative insights in the field where it is applied and their outcomes help us to simplify the problems in other fields. It is in fact true that understanding one kind of complex network might shed light on others. In communication engineering it can be used as tool for practical estimation and dimensioning. A realistic model of a communication network can provide several insights for practical problems. Therefore, network science will always be treated as a practical tool for addressing the problems of communication engineering and its networks.

KEY TERMS AND DEFINITIONS

Communication Engineering: This is the branch of electrical engineering that deals with the principles and applications of communication processes.

Communication Networks: These are the networks which facilitate the communication between two distant communicators.

Complexity: Complexity is the lack of simplicity in a system. Complex systems need sophisticated tools to analyze them.

Network: A network is a combination of nodes and links. The nodes function as the source or processor of information and the links work as the communicator between the nodes.

Network Cost Estimation: This is a detailed method of estimation of the costs of different types of networks using logical methods.

Network Dimensioning: In network dimensioning, all the requirements of a network such as number of network components, bandwidth, and cost parameters are determined using the basic principles of communication engineering.

Network Science: This is the emerging branch of science which deals with the study and analysis of networks to explain the complexities.

Statistical Modeling: Statistical modeling is the process or combination of processes in which the statistical information play the key roles.

Application of Biogeography-Based Optimization to Antennas and Wireless Communications

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The Evolutionary Algorithms (EAs) mimic behaviour of biological entities and they are inspired from Darwinian evolution in nature. The EAs have been extensively studied and applied to several real-world engineering problems. Biogeography-based optimization (BBO) (Simon, 2008) is a recently introduced evolutionary algorithm. BBO is based on mathematical models that describe how species migrate from one island to another, how new species arise, and how species become extinct. The way the problem solution is found is analogous to nature's way of distributing species. In the BBO approach there is a way of sharing information between solutions (Simon, 2008), similar to the other evolutionary algorithms such as GAs, DE, and PSO. This feature makes BBO suitable for the same types of problems that the other algorithms are used for, namely high-dimensional data. Additionally, BBO has some unique features, which are different from those found in the other evolutionary algorithms. For example, quite different from GAs, DE and PSO, the set of the BBO's solutions is maintained from one generation to the next and is improved using the migration model, where the emigration and immigration rates are determined by the fitness of each solution. These differences can make BBO outperform other algorithms (Simon, 2008). BBO has been applied successfully to several real world engineering problems (Ashrafinia, Pareek, Naeem, & Lee, 2011; Bhattacharya & Chattopadhyay, 2010; Boussaïd, Chatterjee, Siarry, & Ahmed-Nacer, 2011; S. K. Goudos et al., 2012; Jamuna & Swarup, 2011; Kankanala, Srivastava, Srivastava, & Schulz; Mandal, Bhattacharya, Tudu, & Chakraborty, 2011; Rathi, Agarwal, Sharma, & Jain, 2011; Silva, dos S Coelho, & Freire, 2010).

The purpose of this chapter is to briefly describe the BBO algorithm and present its application to antenna and wireless communications design problems. This chapter presents results from design cases that include patch antenna, linear antenna array, and a Partial Transmit Sequence (PTS) scheme for OFDM signals based on BBO. The chapter is supported with an adequate number of references. This chapter is subdivided into five sections. The "Background" Section presents the issues, problems, and trends with BBO. Then we briefly present the main BBO algorithm. In the next Section, we describe the design cases and present the numerical results. An outline of future research directions is provided in the following Section while in the "Conclusion" Section we conclude the chapter and discuss the advantages of using a BBO-based approach in the design and optimization of wireless systems and antennas. Finally, an "Additional Reading Section" gives a list of readings to provide the interested reader with useful sources in the field.

DOI: 10.4018/978-1-7998-3479-3.ch066

BACKGROUND

The mathematical models of Biogeography are based on the work of Robert MacArthur and Edward Wilson in the early 1960s. Using this model, they have been able to predict the number of species in a habitat. The habitat is an area that is geographically isolated from other habitats. The geographical areas that are well suited as residences for biological species are said to have a high habitat suitability index (HSI). Therefore, every habitat is characterized by the HSI which depends on factors like rainfall, diversity of vegetation, diversity of topographic features, land area, and temperature. Each of the features that characterize habitability is known as suitability index variables (SIV). The SIVs are the independent variables while HSI is the dependent variable.

Similar to the other evolutionary algorithms (EAs) such as Genetic Algorithms (GAs), Particle Swarm Optimization (PSO), Artificial Bee Colony (ABC) optimization, in the BBO approach there is a way of sharing information between solutions (Simon, 2008). This feature makes BBO suitable for the same types of problems that the other algorithms are used for, namely high-dimensional data. Additionally, BBO has some unique features that are different from those found in the other evolutionary algorithms. For example, quite different from GAs, Ant Colony Optimization (ACO) and PSO, from one generation to the next the set of the BBO's solutions is maintained and improved using the migration model, where the emigration and immigration rates are determined by the fitness of each solution. BBO differs from PSO in the fact that PSO solutions do not change directly; the velocities change. The BBO solutions share directly their attributes using the migration models. The migration operator provides BBO with a good exploitation ability. These differences can make BBO outperform other algorithms (Ma, 2010; Ma, Simon, Fei, & Chen, 2013; Simon, 2008). It must be pointed out if PSO or ABC are constrained to discrete space then the next generation will not necessarily be discrete (Ma et al., 2013). However, this is not true for BBO; if BBO is constrained to a discrete space then the next generation will also be discrete to the same space. As the authors in (Ma et al., 2013) suggest this indicates that BBO could perform better than other EAs on combinatorial optimization problems, which makes BBO suitable for application to the PTS problem. The main computational cost of EAs is in the evaluation of the objective function. The BBO mechanism is simple, like that of PSO and ABC. Therefore, for most problems, the computational cost of BBO and other EAs will be the same since it will be dominated by objective function evaluation (Ma, 2010). More details about the BBO algorithm can be found in (Ma et al., 2013; Simon, 2008).

BIOGEOGRAPHY-BASED OPTIMIZATION ALGORITHM

Therefore, a solution to a D-dimensional problem can be represented as a vector of SIV variables $[SIV_1, SIV_2, \dots, SIV_D]$, which is a habitat or island. The value of HSI of a habitat is the value of the objective function that corresponds to that solution and it is found by

$$HSI = F(\text{habitat}) = F(SIV_1, SIV_2, \dots, SIV_D)$$

Habitats with a high HSI are good solutions of the objective function, while poor solutions are those habitats with a low HSI. The habitats with high HSI are those that have large population and high emigration rate μ . For these habitats, the immigration rate λ is low. The immigration and emigration rates

are functions of the rank of the given candidate solution. The rank of the given candidate solution represents the number of species in a habitat. These are given by

$$\mu_k = E \left(\frac{k}{S_{\max}} \right), \quad \lambda_k = I \left(1 - \frac{k}{S_{\max}} \right)$$

here I is the maximum possible immigration rate, E is the maximum possible emigration rate, k is the rank of the given candidate solution, and $S_{\max}$ is the maximum number of species (e.g. population size). The rank of the given candidate solution or the number of species is obtained by sorting the solutions from most fit to least fit, according to the HSI value (e.g. fitness). That is the best candidate solution has a rank of $S_{\max}$ and the worst candidate solution has a rank of one. BBO uses both mutation and migration operators. The application of these operators to each SIV in each solution is decided probabilistically. In each generation, there is a probability $P_{\text{mod}} \hat{I} [0, 1]$ that each candidate solution will be modified by migration. P_{mod} is a user-defined parameter that is typically set to a value close to one, and is analogous to crossover probability in GAs. That is the migration operator in each generation is applied only if P_{mod} is greater than a random number generated from a uniform distribution from the interval $[0,1)$.

The migration for NP habitats can be described as follows:

Algorithm 1. Habitat migration

- 1: for $i=1$ to NP
- 2: Select with probability based on
- 3: if then
- 4: for $j=1$ to NP
- 5: Select with probability based on
- 6: if then
- 7: Randomly select a SIV from
- 8: Replace a random SIV in with
- 9: end if
- 10: end for
- 11: end if
- 12: end for

The X_i in the above algorithm is habitat i . The information sharing between habitats is accomplished using the immigration and emigration rate. The λ_i is proportional to the probability that SIVs from neighboring habitats will migrate into habitat X_i . The μ_i is proportional to the probability that SIVs from habitat X_i will migrate into neighboring habitats.

The mutation rate m of a solution S is defined to be inversely proportional to the solution probability and it is given by

$$m_S = m_{\max} \left(\frac{1 - P_s}{P_{\max}} \right)$$

where P_s is the probability that a habitat contains S species (e.g. the rank of the solution is S), $P_{\max}$ is the maximum P_s value over all $s \in [1, S_{\max}]$, and $m_{\max}$ is a user-defined parameter.

Mutation can be described as follows:

Algorithm 2. Habitat mutation

- 1: for $i=1$ to NP
- 2: Compute the probability
- 3: Select SIV with probability based on
- 4: if then
- 5: Replace with a randomly generated SIV
- 6: end if
- 7: end for

The m_i in the above algorithm is the mutation rate of solution i . As with other evolutionary algorithms, BBO also incorporates elitism. This is implemented with a user-selected elitism parameter p . This means that the p best solutions remain from one generation to the other.

APPLICATIONS, RESULTS, AND DISCUSSION

In this Section, we provide representative wireless communications design problems that are solved with the BBO algorithm. First, we present an example case of linear array synthesis by reducing the number elements required. The second example is that of an arbitrary-shaped patch antenna which can be used for satellite communications. The third example uses the BBO algorithm for addressing a common problem in wireless communication system, the reduction of peak to average power ratio (PAPR) of transmitted signals.

Reducing the Number of Elements in Linear Arrays Using BBO

Several applications of modern wireless communications systems require radiation characteristics such as higher directivity that cannot be achieved by using a single antenna. The use of antenna arrays is the obvious solution for such a case. Among others, antenna arrays are employed for several radar and wireless communications applications in space and on earth. Their advantages include the possibility of fast scanning and precise control of the radiation pattern.

Synthesis of linear antenna arrays has been extensively studied in the last decades using several analytical or stochastic methods. The linear array design problem is multimodal and therefore requires the use of an optimization method that does not easily get trapped in local minima. The reduction of array elements plays an important role in cases where the cost, weight and size of antennas are limited. Therefore, a common goal in array synthesis is the generation of a desired pattern using the minimum number of elements. Additional constraints could include the minimum and maximum distance between two adjacent elements.

We assume a $2N+1$ -element linear array, which is symmetrically placed along the x-axis, see Figure 4.

We examine the synthesis of a pattern taken from the literature. We assume that $d_{\min} = 0.5\lambda$, and $d_{\max} = \lambda$, where $d_{\min}, d_{\max}$ is the minimum and maximum distance between two adjacent elements respectively.

Figure 1. Geometry of the antenna array.

The desired pattern in this case is that of a 29-element Taylor-Kaiser array uniformly spaced with $d = 0.5\lambda$, $SLL_d = -25$ dB, and $BW_d = 11.8^\circ$. The authors in (Yanhui, Zaiping, & Qing Huo, 2008) use a non-iterative synthesis method which is based on the matrix pencil method (MPM) (S. Yang, Y. Liu, & Liu, 2009; Yanhui, Qing Huo, & Zaiping, 2010; Yanhui et al., 2008). We set the habitat modification probability, P_{mod} , to 1 and the maximum mutation rate, m_{max} , equal to 0.001. The maximum immigration rate I, and the maximum emigration rate E are both set both to one. The elitism parameter p is set to two. The population size and the number of generations is set to 100 and 2000 respectively.

We run the algorithm for two cases with 17 and 18 elements respectively

The results from the literature are for $N=17$ (Yanhui et al., 2008), and $N=18$ (Wenji, Lian, & Fang, 2011), elements respectively. Therefore, we obtain reconstructed patterns for both cases. The radiation pattern characteristics are reported in Table 1. We notice that BBO found slightly better results than the one in (Yanhui et al., 2008) for the 17-element case. The peak SLL is better while the beamwidth is the same as that of the desired pattern. The value of MSE is also better. For the 18-element case, BBO outperforms (Wenji et al., 2011). The SLL is improved and the beamwidth exactly matches the desired pattern. The MSE is improved by two orders of magnitude compared with (Wenji et al., 2011).

Table 1. Comparative radiation pattern characteristics for the 29-element array design case

	Desired	MPM (Yanhui et al., 2008) N=17	BBO N=17	MPM (Wenji et al., 2011) N=18	BBO N=18
SLL (dB)	-26.10	-25.96	-25.98	-25.57	-26.04
BW (deg)	11.80	11.80	11.80	12.00	11.80
MSE	n/a	9.586e-7	6.260e-7	2.651e-5	4.192e-7

Arbitrary-shaped Dual Band Patch-Antenna Design Using the BBO Algorithm

The use of microstrip patch antennas in wireless communication systems provides several advantages like low profile, low cost, and ease of fabrication. Patch antennas or arrays of such antennas in the Ku-band have practical applications in radars (Bilgic & Yegin, 2014), and satellite communications (Huayan et al., 2014; Sharma, Yadav, Kumar, Ranga, & Bhatnagar, 2011; Zhang, Mahe, & Razban, 2014).

The next design case is that of arbitrary-shaped dual band patch antenna. Figure 3 shows the patch geometry. It consists of a 5X5 grid where the blue indicates the existence of metal and the white indicates

Figure 2. Synthesis of a 29-element Taylor-Kaiser pattern with $SLL = -25\text{dB}$ with $N= 17$ and $N=18$ elements using BBO

dielectric. The grid is numbered from 1 to 25 as it is shown in the figure. The patch antenna is fabricated on a dielectric substrate with $\epsilon_r = 3.38$ and 30mils thick. Aperture coupled feed is used and an H-shaped slot is created in the ground plane. The design goal is to minimize the S11 magnitude in two frequencies 12GHz and 14GHz. For this case, the population size is set to 10 vectors and the maximum

Figure 3. Arbitrary-shaped patch (a) geometry. The blue boxes indicate presence of metal. (b) best antenna found by BBO

Figure 4. Simulated surface current distribution of the best design found by BBO (a) at 12 GHz, (b) at 14 GHz.

Figure 5. Simulated S_{11} curve for the best design found by BBO.

number of iterations is set to 200. We run the BBO algorithm for 20 independent trials. The surface current distributions for the best-obtained design and the geometry are shown in Figure 4. Figure 5 presents the frequency response of the best design. The BBO obtained antenna has a $|S_{11}| < -10\text{dB}$ bandwidth between 11.35 and 12.78 GHz and from 13.51GHz to 14.37GHz. The S_{11} values at 12 and 14 GHz are found to be -28.45 and -27.59 respectively.

A PTS Technique Based on BBO for PAPR Reduction of OFDM Signals

Orthogonal frequency division multiplexing (OFDM) is widely used in several high-bit-rate digital communication systems such as Digital Audio Broadcasting (DAB), Digital Video broadcasting (DVB) and wireless local area networks (Hara & Prasad, 1997; Van Nee & Prasad, 2000). OFDM systems still have several research challenging issues. A major drawback of OFDM signals is the high value of peak to average power ratio (PAPR). Thus, it is important to reduce the PAPR of OFDM signal in order to fully utilize the OFDM technical features. Partial transmit sequences (PTS) (Cimini Jr & Sollenberger, 2000), is a popular PAPR reduction method with good PAPR reduction performance. However, PTS requires an exhaustive search in order to find the optimal phase factors. Thus, the search complexity is high. Several methods have been published in the literature for PAPR reduction using PTS with low search complexity

In an OFDM system, the high-rate data stream is split into N low-rate data streams that are simultaneously transmitted using N subcarriers. The discrete-time signal of such a system is given by

$$s_k = \frac{1}{\sqrt{N}} \sum_{n=0}^{N-1} S_n e^{j \frac{2\pi nk}{LN}} \quad k = 0, 1, \dots, LN - 1$$

where L is the oversampling factor, $\mathbf{S} = [S_0, S_1, \dots, S_{N-1}]^T$ is the input signal block. Each symbol is modulated by either phase-shift keying (PSK) or quadrature amplitude modulation (QAM).

In the PTS approach the $\mathbf{S}$ input data OFDM block is partitioned into M disjointed subblocks represented by the vector $\mathbf{S}_m$ $m = 1, 2, \dots, M - 1$ and oversampled by inserting $(L - 1)N$ zeros. Next, the subblocks are converted to time domain using LN point inverse fast fourier transform (IFFT). The PTS objective is to produce a weighted combination of the M subblocks using $\mathbf{b} = [b_1, b_2, \dots, b_M]^T$ complex phase factors to minimize PAPR. In order to reduce the search complexity the phase factor possible values are limited to a finite set. The set of allowable phase factors is

$$A = \left\{ e^{j \frac{2\pi n}{W}} \mid n = 0, 1, \dots, W - 1 \right\}$$

where W is the number of allowed phase factors. Therefore in case of M subblocks and W phase factors the total number of possible combinations is W^M . In order to reduce the search complexity we usually set fixed one phase factor.

The block diagram of the PTS technique is shown in Figure 6.

The optimization goal of the PTS scheme is to find the optimum phase combination for minimum PAPR. Thus, the objective function can be expressed as

Minimize

Figure 6. Block diagram of the PTS technique

$$F(\mathbf{b}) = 10 \log_{10} \frac{\max_{0 \leq k \leq LN-1} |\mathbf{s}'(\mathbf{b})|^2}{E[|\mathbf{s}'(\mathbf{b})|^2]}$$

subject to

$$\mathbf{b} \in \left\{ e^{j\phi_m} \right\}^M \text{ where } \phi_m \in \left\{ \frac{2\pi l}{W} \mid l = 0, 1, \dots, W-1 \right\}$$

We have evaluated the objective function above using different evolutionary algorithms and methods found in the literature. We have used two main measurement criteria namely the complementary cumulative distribution function (CCDF) and the computational complexity. In all our simulations, 10E5 random OFDM blocks are generated. The transmitted signal is oversampled by a factor $L=4$. We consider 16-QAM modulation with $N=256$ sub-carriers which are divided into $M=16$ random subblocks. The phase factors for $W=2$ are selected. We consider the first phase factor to be fixed so the total number of unknown phase factors is $M-1$. Figures 7a and 7b show the comparison between the CCDF by BBO-PTS and other PTS reduction techniques. For $\Pr(PAPR > PAPR_0) = 10^{-3}$ the PAPR of the original OFDM transmitted signal is 10.84dB. For all evolutionary algorithms, the population size NP is set to 30 and the maximum number of generations G is set to 30. Thus, the computational complexity of BBO-PTS for this case is $NP \times G = 900$. The PAPR by the BBO-PTS is 6.32dB. The computational complexity of the exhaustive search is $W^{M-1} = 32768$ while the PAPR for this case is 5.86dB. The PAPR by the iterative flipping algorithm for PTS (IPTS) (Cimini Jr & Sollenberger, 2000) is 7.55dB with search complexity $(M-1)W=30$. The PAPR by the gradient descent method (GD) (Han & Lee, 2004) with search

complexity $C_{M-1}^r W^r I = C_{15}^2 2^2 3 = 1260$ is 6.96dB. We also use the Random Search (RS) (Cimini Jr & Solenberger, 2000) method by selecting 900 random phase factors. The PAPR for this case is 6.37dB. The PAPR by Artificial Bee Colony (ABC) PTS (Y. Wang, Chen, & Tellambura, 2010), Particle Swarm Optimization (PSO) PTS (Wen, Lee, Huang, & Hung, 2008), and Ant Colony Optimization (ACO) PTS (Dorigo & Stutzle, 2004), is 7.01dB, 7.13dB, and 6.52dB, respectively.

Figure 7. a) PARP reduction performance comparison of BBO-PTS algorithm with other PTS schemes for $NP=30$, $G=30$. b) Zoom in view of PARP reduction performance comparison of BBO-PTS.

FUTURE RESEARCH DIRECTIONS

The research domain of biogeography-based optimization is growing rapidly. Several extensions of the original algorithm have been emerged. Among others a trend in BBO research is to use different migration models like curve shapes (Ma & Simon, 2011a), and blended migration (Ma & Simon, 2011b). A performance comparison of different migration models is given in (Guo, Wang, & Wu, 2014) and in (Ma, 2010). Other BBO variants proposed include (Ma & Simon, 2011a), blended migration (Ma & Simon, 2011b), oppositional BBO (Roy & Mandal, 2011), real-coded BBO (Gong, Cai, Ling, & Li, 2010), chaotic BBO (Saremi, Mirjalili, & Lewis, 2014), and BBO with a polyphyletic migration operator (Xiong, Shi, & Duan, 2014).

BBO hybrids with other algorithms is also a growing research trend. BBO has been combined with Differential Evolution (DE) (Gong, Cai, & Ling, 2011), with evolutionary strategies (Du, Simon, & Ergezer, 2009), with Harmony Search (HS) algorithm (G. Wang et al., 2013), and local search methods (Feng et al., 2013). The application of multi-objective BBO algorithms (Costa E Silva, Coelho, & Lebensztajn, 2012; Jamuna & Swarup, 2012; Li & Yin, 2013) to antenna and wireless design problems introduces new challenges regarding performance and computational cost. Recently a novel Multi-objective BBO algorithm has been applied to wireless networks design (Sotirios K. Goudos, Plets, Liu, Martens, & Joseph, 2015). Moreover, a chaotic BBO algorithm was applied in (Tegou et al., 2018) for spectrum allocation in cognitive radio networks. The problem of antenna selection in Multiple Input Multiple Output (MIMO) systems is solved in (Fountoukidis et al., 2018) using BBO variants. Additionally, real-coded BBO is applied by the authors in (Paraskevopoulos, Dallas, Siakavara, & Goudos, 2017) for cognitive engine design. Therefore, new research directions have to be explored.

CONCLUSION

In this chapter, we discussed and evaluated the application of BBO optimizers to antenna and wireless communications design problems. BBO is a recently introduced global stochastic optimizer that is based on mathematical models of species migration. Our results show the efficiency of this approach for antenna synthesis. In the design case presented here, the BBO results are better than those found in the literature. The BBO algorithm has been applied to the design of an arbitrary-shaped patch antenna. The obtained best design is quite efficient in both frequencies. Additionally we have used BBO a new low complexity PTS scheme. The comparison with other existing PTS reduction methods shows that BBO-PTS performs better than other methods with the same computational complexity. Simulation results show that BBO-PTS is an efficient and powerful tool for PAPR reduction of OFDM signals.

Recent BBO algorithms and their application to wireless communications problems will be part of our future work. The BBO algorithms can be valuable tools for constrained single or multi-objective optimization problems in antennas and wireless communications.

KEY TERMS AND DEFINITIONS

Digital Audio Broadcasting (DAB): A digital radio technology for broadcasting radio stations.

Digital Video Broadcasting (DVB): A suite of internationally accepted open standards for digital television.

Genetic Algorithms: A stochastic population-based global optimization technique that mimics the process of natural evolution.

Mainlobe Beamwidth: In a radio antenna's radiation pattern, the main lobe, or main beam is the lobe containing the maximum power. The beamwidth of the main lobe is the width of the main lobe specified by the angles between the points on the side of the lobe where the power has fallen to zero.

Orthogonal Frequency-Division Multiplexing (OFDM): A method of encoding digital data on multiple carrier frequencies.

Sidelobe Level (SLL): The ratio, usually expressed in decibels (dB), of the amplitude at the peak of the main lobe to the amplitude at the peak of a side lobe.

Wireless Local Area Network (WLAN): A network in which a mobile user can connect to a local area network (LAN) through a wireless (radio) connection. Most modern WLANs are based on IEEE 802.11 standards, marketed under the Wi-Fi brand name.

Bits'-Carrying Capacities of Switched Local Area Networks

INTRODUCTION

All switched Local Area Networks (switched LANs) have a common parameter, known as 'bits-carrying capacity', which is one of the parameters that network managers and administrators use in managing the performances of the networks. In fact, every network has a limited bits'-carrying capacity; and, an increase in a network's response time, which is a measure of the time between when a user requests a service and the time when the service is granted, is an indication that a network is operating above its bits'-carrying capacity (Forouzan, 2008, p. 876). Knowing the bits'-carrying capacity of any network is therefore, very important with respect to operating/managing the network optimally; that is, the ability to operate the network at all times, at, or near, its bits'-carrying capacity. This is because, if a network is operated above its bits'-carrying capacity, its response time increases, leading to a fall in throughput: on the other hand, it is a waste of resources, to operate a network below its bits'-carrying capacity. However, it appears that there is no available, formal method, or formula in literature for determining this parameter. For example, in Chapter 1 of CISCO CCNA Exploration Companion Guide (2018, p. 15), the following advice was offered to LAN Designers/Installers: When selecting switch hardware for a switched LAN, it is necessary to determine which switches are needed in the core, distribution, and access layers - the three-layer hierarchical network design model enunciated by CISCO CCNA Exploration Companion Guide (2018, p. 2) to accommodate the bandwidth requirement of the LAN. The pertinent question that was not answered in this CISCO documentation, and, has not been answered elsewhere is: How should the bandwidth requirement of a LAN be determined? In this Chapter, the derivation of a formula which can be used to obtain the bits' - carrying capacity (usually referred to as bandwidth by some professionals) of any switched LAN is reported. Also reported, is a formula that can be used to obtain the capacity (that is, bits' capacity, in units, such as, Megabits; Gigabits) to subscribe for, whenever a switched LAN needed to be connected to the network of a service provider, such as connecting the LAN to the Internet via an ISP (Internet Service Provider). Illustrative examples applying both formulas are also given.

BACKGROUND

A common networks' management metric that should always be monitored by the application programs which are used to manage the operations of computer networks is the bits'-carrying capacities. Every

DOI: 10.4018/978-1-7998-3479-3.ch067

network has a limited bits'-carrying capacity, and one of the functions, according to Forouzan (2008, p. 876), of a network management system (software) is ensuring that a network is not operated above its bits'-carrying capacity (see also, Rathi, N. Malik, Chahal, & S. Malik, 2014; Zubair, Ahmad, Faraz Ahmad, & Ali, 2014).

Bandwidth-Delay Product (BDP) is the term given to the bits'-carrying capacity of a single link (or bits' pipe) in a network; and, is a quantity obtained by multiplying the bandwidth of the link in bits/second, with the round-trip time (RTT) in seconds (that is, the propagation-delay of the link multiplied by 2). The BDP of a link is a very useful quantity to keep in mind when analyzing the performance of computer-communication networks; because, the BDP as defined by Forouzan (2008, p. 93), is the capacity of the bit-pipe from a transmitter to a receiver, and back to the transmitter (see also, Szymanski, 2016; Rangaswamy & Krishnareddy, 2015; Tanenbaum, 2006, p.559). As an example, if the BDP of a bit-pipe is 60 million bits, a transmitter at one end of the pipe would need to transmit a 60 million bits burst to be able to keep transmitting at maximum rate, until it receives the first acknowledgement: in order words, this is the number of bits it takes to fill the pipe. (Tanenbaum, 2006, p.559) In the words of Kai et al. (2004), BDP-UB (Bandwidth Delay Product – Upper Bound) is a path's upper-bound BDP, and this according to the paper, can be considered as a path's maximum packets (bits) carrying capacity. Attempting to operate a network above its BDP-UB does not lead to the achievement of additional throughput; instead, a fall in throughput occurs when more bits than the BDP-UB are injected into the network. (Kai et al. 2004; Gerd, 1989, p.203) Therefore, it is apparent that, knowing the bits'-carrying capacity of any network is very important for the optimal operation of the network. Comer (2004, p.247) in this context, has averred that network administrators and managers are generally agreed on the position that, networks should not be operated above 90% of their bits'-carrying capacities.

FOCUS OF THE ARTICLE

Deriving from the points-of-views that were highlighted in the previous sections, the following main question becomes pertinent: How therefore, should the bits'-carrying capacities of switched LANs be determined? Switched LANs to the best of the knowledge of the research team involved in this work are just arbitrarily installed, without the capacities being known, and, various ad-hoc approaches are usually used for the network management, using network management application programs as the main aids. The research team involved in this work has also not seen it reported in literature, or documented elsewhere of an approach, or, approaches for the determination of the bits'-carrying capacities of switched LANs. Information and Communication Technology (ICT) Managers/Administrators of the Networks of organizations, and, switched LANs Designers/Installers, also appear not to have formal basis for the determination of the bits' capacities (which some erroneously refer to as bandwidths – erroneous because, the unit of interest in this context, is bits, and not, bits/second), which they should advise the management of the organizations they are working for to purchase from Service Providers like ISPs, for Internet access purposes. The capacity (in bits) requirement of any organization for the purpose of Internet access is unarguably, a function of the capacity of the installed base of its LAN – that is, how large the LAN is in terms of the number of its connected end users, which in turn, determines the number of switches that would be installed in the LAN. These ideas are illustrated in Figure 1. From experience subscriptions for bits' capacities has largely been done arbitrarily, using, rule-of-thumb approaches in most cases. The need to provide solutions to these problems was the motivation for the work reported in this article.

Figure 1.

One of the objectives of embarking on researches in this area, which has produced as one of its results, the formulas that are hereunder reported in this article, is the development of methodologies and algorithms, which are of practical utility for solving the performance problems of data communication networks generally, and switched LANs in particular. This stems from the almost non availability of methodologies and algorithms/formulas that can be practically utilized for solving problems associated with this class of networks. In this context, Tanenbaum (2006, p.557) once observed that, understanding network performance is unfortunately more of an art than a science; that, there is little underlying theory which is actually of any use in practice; and that, the best researchers and practitioners can do in this situation is, give rules-of-thumb gained from hard experience, and, present examples taken from the real world. Therefore, in attempting to meet the foregoing objective, this work sought to promote the merger of some level of mathematical elegance, with techniques that are of practical importance.

SOLUTIONS AND RECOMMENDATIONS

This section of the article reports the derivation of formulas that can be used to: 1) calculate the bits'-carrying capacity of any switched LAN, 2) calculate the capacity in bits, for example, Mbits, Gbits, that should be subscribed for (or bought), when it is necessary to connect a switched LAN to the network of an ISP, for the purpose of providing Internet access services to the organization that owns the switched LAN installation. Through an illustrative, real-world example, the need to obtain optimal values of bits'-carrying capacities, and, capacities in bits to be subscribed for, or bought, were recommended.

Derivation of a Formula for the Computation of the Bits'-Carrying Capacities of Switched LANs

Eyinagho et al. (2011), have shown that any switched LAN's end-to-end delays should be enumerated with respect to the switches (nodes) of which the LAN is composed; and, also posited that it is wrong to do the enumeration with respect to the users' hosts (end devices) that are attached to the LAN. How this enumeration should be carried out was illustrated in (Eyinagho, 2012, pp. 24-30): furthermore, the development of a generic maximum delay model of a packet switch, which can be used to compute all the maximum end-to-end delays of any switched LAN, was reported in (Eyinagho, Falaki, & Atayero, 2012, pp. 76-94). According to Metro-Ethernet-Forum (2016), for any bits'-pipe (or link) in a data communication network, bandwidth (BW) is given as:

$$BW \leq \frac{Capacity}{Round-Trip\ Time} \Rightarrow Round-Trip\ Time \times BW \leq Capacity \text{ or } Capacity \geq Round-Trip\ Time (RTT) \times BW \quad (1)$$

Here, BW is the bits'-pipe or communication link's transmission rate (in bits/second); RTT is the time (in seconds) taken for a bit to travel from one end of the pipe or link to the other end, and back; while, Capacity, is the number of bits 'in flight' across the pipe. Stated more succinctly in the context of (1), the Capacity of the pipe refers to the maximum number of bits that can be in transit across it in the time interval, RTT. The implication of (1) is that, lower bound on Capacity = upper-bound on (RTT × BW). However, BW, which is the pipe or link's transmission rate, is a fixed quantity. It therefore, follows that (1) can be restated thus:

$$\text{minimum Capacity} = \text{maximum RTT} \times BW \text{ (a constant)} \quad (2)$$

which can be put simply as:

$$Capacity = BW \times RTT = \text{bandwidth-delay product (BDP)} \quad (3)$$

Capacity in (3) is understood from (2) to be the minimum bits'-carrying capacity that is desired for a link or bits'-pipe; while RTT is the pipe or link's traversing bit, maximum round-trip time. What has generally been reported in literature for the determination of the bits'-carrying capacity of a single, bits'-pipe or link in switched networks is (3); see, for example (Szymanski, 2016; Forouzan, 2008, p. 93; Ryousei, Yuetsu, Tomohiro, Motohico, & Fumihiro, 2006; Tanenbaum, 2006, p. 559; Kai, Yuan, Samarth, & Klara, 2004). This equation is called, 'bandwidth-delay product' (BDP). Switched LANs however, generally consists of several, bits'-pipes or links, interconnected by various switches to form several origin-destination paths. Assume it is desired to have such a LAN, with n switches installed, or desired to be installed, based on the number of users' hosts to be interconnected by the LAN, and the locations of these hosts. Eyinagho, Falaki, and Atayero (2012, p. 134) proposed (4), called the Eyinagho-Falaki maximum end-to-end delay matrix for switched LANs; and, it is a generic maximum end-to-end delay matrix for this class of LANs. With respect to (4), n = the number of switches in a switched LAN; $meted_{ir}$ = maximum end-to-end delay between any host that is connected to switch i and any other host that is connected to switch r; $meted_{ll}$ = maximum end-to-end delay between any two

hosts that are connected to switch 1; $meted_{22}$ = maximum end-to-end delay between any two hosts that are connected to switch 2; ...;

$$\begin{array}{c}
 \begin{array}{cccc}
 & switch1 & switch2 & \dots & switch(n-1) & switch n \\
 switch1 & \left[\begin{array}{ccccc}
 meted_{11} & & & & \\
 meted_{21} & meted_{22} & & & \\
 \vdots & \vdots & \vdots & \vdots & \vdots \\
 meted_{(n-1)1} & meted_{(n-1)2} & \dots & meted_{(n-1)(n-1)} & \\
 meted_{n1} & meted_{n2} & \dots & meted_{n(n-1)} & meted_{nn}
 \end{array} \right]
 \end{array}
 \end{array} \quad (4)$$

$meted_{nn}$ = maximum end-to-end delay between any two hosts that are connected to switch n respectively. If M_{ij} = maximum end-to-end delay of the path connecting origin switch i to destination switch j;

μ_{ij} = total traffic of a subset of the hosts that are connected to switch i to a subset of the hosts that are connected to switch $j \leq$ bandwidth of the path connecting origin switch i to destination switch j (5)

That is, $M_n = (M_{ij})$, and $\mu_n = (\mu_{ij})$, $i=1,2,3,\dots,n$; $j=1,2,3,\dots,n$, is $n \times n$ end-to-end delay matrix, and $n \times n$ bandwidth matrix respectively. It will be shown in this paper that, the capacity of any switched LAN is given by $Tra(M_n \mu_n) = Tra(\mu_n M_n)$; where, $Tra(AB)$ is the trace of the product of matrix **A** and **B**. Therefore,

$$M_n \times \mu_n = \begin{bmatrix} M_{11} & M_{12} & \dots & M_{1n-1} & M_{1n} \\ M_{21} & M_{22} & \dots & M_{2n-1} & M_{2n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ M_{n-11} & M_{n-12} & \dots & M_{n-1n-1} & M_{n-1n} \\ M_{n1} & M_{n2} & \dots & M_{nn-1} & M_{nn} \end{bmatrix} \times \begin{bmatrix} \mu_{11} & \mu_{12} & \dots & \mu_{1n-1} & \mu_{1n} \\ \mu_{21} & \mu_{22} & \dots & \mu_{2n-1} & \mu_{2n} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ \mu_{n-11} & \mu_{n-12} & \dots & \mu_{n-1n-1} & \mu_{n-1n} \\ \mu_{n1} & \mu_{n2} & \dots & \mu_{nn-1} & \mu_{nn} \end{bmatrix} \quad (6)$$

The matrix M_n is (4) completed with elements above the leading diagonal; because, elements above and below the leading diagonal are mirror images of each other. Meanwhile, let it be assumed that a hypothetical switched LAN has 2 switches; (6) will become,

$$M_2 \times \mu_2 = \begin{bmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{bmatrix} \times \begin{bmatrix} \mu_{11} & \mu_{12} \\ \mu_{21} & \mu_{22} \end{bmatrix} = \begin{bmatrix} M_{11}\mu_{11} + M_{12}\mu_{21} & M_{11}\mu_{12} + M_{12}\mu_{22} \\ M_{21}\mu_{11} + M_{22}\mu_{21} & M_{21}\mu_{12} + M_{22}\mu_{22} \end{bmatrix}$$

$$Tra(M_2 \mu_2) = M_{11}\mu_{11} + M_{12}\mu_{21} + M_{21}\mu_{12} + M_{22}\mu_{22} \quad (7)$$

The maximum end-to-end delay of a path in the direction $i \rightarrow j$ is however, the same as the maximum end-to-end delay of the path in the direction $j \rightarrow i$, therefore, $M_{ij} = M_{ji}$; for example, $M_{12} = M_{21}$. It is also, easy to see that the upper bound in (5) is the bandwidth of the path connecting origin switch i to destination switch j, therefore, $\mu_{ij} = \mu_{ji}$. Consequently, replacing M_{ij} with M_{ji} and μ_{ij} with μ_{ji} in (7), gives,

$$\text{Tra}(\mathbf{M}_2\boldsymbol{\mu}_2) = M_{11}\mu_{11} + M_{12}\mu_{12} + M_{12}\mu_{12} + M_{22}\mu_{22}$$

$$\text{Tra}(\mathbf{M}_2\boldsymbol{\mu}_2) = M_{11}\mu_{11} + 2M_{12}\mu_{12} + M_{22}\mu_{22} \quad (8)$$

It is easily seen that, the product of the maximum delay (in seconds) that a bit will incur inside any switch (whether, input-queued, output-queued, or input-output queued) and the rate at which the switch transmits bits at the output port (in bits/sec.) is the bits'-carrying capacity of the switch. This implies that at full capacity, when bits are not being transmitted by the switch, that is, it is on vacation, any incoming bit will be dropped. If therefore, M_{ii} (in seconds) is the maximum delay of a bit in switch i , and μ_{ii} (in bits/sec.) is the maximum rate at which the switch transmits bits, the bits'-carrying capacity of such a switch will be given as $M_{ii}\mu_{ii}$ (bits). Therefore, the capacity of switch 1 is $M_{11}\mu_{11}$ (bits), and $M_{22}\mu_{22}$ (bits) is the capacity of switch 2. However, the capacity of the link connecting the two switches is given by (2), which is, $2M_{12}\mu_{12}$ (the BDP of the link); where, $2M_{12}$ is the maximum round-trip time of the link connecting switches 1 and 2, while the maximum bandwidth of this link is μ_{12} . Hence, the capacity of a 2-switch LAN, which is illustrated in Figure 2, and denoted as CP_2 is given by (8). Similarly, it can be shown that, $\text{Tra}(\boldsymbol{\mu}_2\mathbf{M}_2) = M_{11}\mu_{11} + 2M_{12}\mu_{12} + M_{22}\mu_{22}$; as, it is known generally that, for two square matrices $\mathbf{A}$ and $\mathbf{B}$, $\text{Tra}(\mathbf{AB}) = \text{Tra}(\mathbf{BA})$.

Figure 2.

Likewise, for a 3 switch LAN

$$\mathbf{M}_3 \times \boldsymbol{\mu}_3 = \begin{bmatrix} M_{11} & M_{12} & M_{13} \\ M_{21} & M_{22} & M_{23} \\ M_{31} & M_{32} & M_{33} \end{bmatrix} \times \begin{bmatrix} \mu_{11} & \mu_{12} & \mu_{13} \\ \mu_{21} & \mu_{22} & \mu_{23} \\ \mu_{31} & \mu_{32} & \mu_{33} \end{bmatrix}$$

$$= \begin{bmatrix} M_{11}\mu_{11} + M_{12}\mu_{21} + M_{13}\mu_{31} & M_{11}\mu_{12} + M_{12}\mu_{22} + M_{13}\mu_{32} & M_{11}\mu_{13} + M_{12}\mu_{23} + M_{13}\mu_{33} \\ M_{21}\mu_{11} + M_{22}\mu_{21} + M_{23}\mu_{31} & M_{21}\mu_{12} + M_{22}\mu_{22} + M_{23}\mu_{32} & M_{21}\mu_{13} + M_{22}\mu_{23} + M_{23}\mu_{33} \\ M_{31}\mu_{11} + M_{32}\mu_{21} + M_{33}\mu_{31} & M_{31}\mu_{12} + M_{32}\mu_{22} + M_{33}\mu_{32} & M_{31}\mu_{13} + M_{32}\mu_{23} + M_{33}\mu_{33} \end{bmatrix}$$

$$\text{Tra}(\mathbf{M}_3\boldsymbol{\mu}_3) = M_{11}\mu_{11} + M_{12}\mu_{21} + M_{13}\mu_{31} + M_{21}\mu_{12} + M_{22}\mu_{22} + M_{23}\mu_{32} + M_{31}\mu_{13} + M_{32}\mu_{23} + M_{33}\mu_{33}$$

By adopting the same reasoning as was explained previously, we have, $M_{12}=M_{21}$, $M_{13}=M_{31}$, $M_{23}=M_{32}$, $\mu_{12}=\mu_{21}$, $\mu_{13}=\mu_{31}$, $\mu_{23}=\mu_{32}$. Hence,

$$\text{Tra}(\mathbf{M}_3\boldsymbol{\mu}_3) = M_{11}\mu_{11} + M_{22}\mu_{22} + M_{33}\mu_{33} + 2M_{12}\mu_{12} + 2M_{13}\mu_{13} + 2M_{23}\mu_{23} \quad (9)$$

Therefore, as was the case above, $M_{11}\mu_{11}$, $M_{22}\mu_{22}$, and $M_{33}\mu_{33}$ are the bits'-carrying capacities of switches, 1, 2 and 3 respectively; while, $2M_{12}\mu_{12}$, $2M_{13}\mu_{13}$, and $2M_{23}\mu_{23}$ are the bits'-carrying capacities of the links or paths between switches 1 and 2, switches 1 and 3, and switches 2 and 3 respectively. Hence, (9), clearly gives the bits'-carrying capacity, CP_3 , of a 3-switch LAN. However, a fundamental property of a network is the bottleneck bandwidth, which sets the upper limit on how quickly the transmitter's data can be delivered to the receiver by the network (Ryousei, Yuetsu, Tomohiro, Motohico, & Fumihiro, 2006; Paxson, 1999); as, according to Lakshman and Upamanyu (1997), the loose definition of BDP is that, it is the product of the RTT (in seconds) for a data connection and the transmission rate (in bits/sec.) of the bottleneck link in the path of that connection. Therefore, assume that each of the links or bits'-pipes on a path or network has bandwidth equal to the smallest link or bits'-pipe's bandwidth, this being the bottleneck link or bits'-pipe: hence, this link's or bits'-pipe's bandwidth is the bottleneck bandwidth on the path or network. It is important in this context to recall here, the minimum capacity postulation with respect to (2). Let it be also assumed that this bottleneck bandwidth upper bounds (5), and that, this bandwidth is denoted by μ . All the bandwidths in (9) can then be replaced with the bottleneck bandwidth; this equation can then be written as:

$$\begin{aligned} CP_3 &= \mu(M_{11} + M_{22} + M_{33} + 2M_{12} + 2M_{13} + 2M_{23}) \\ &= \mu(M_{11} + M_{22} + M_{33} + 2M_{12} + 2M_{13} + 2M_{23}) \end{aligned}$$

In a similar fashion, the capacity of a 2 switch LAN is, $CP_2 = \mu(M_{11} + M_{22} + 2M_{12})$; and the capacity of a 4 switch LAN is

$$CP_4 = \mu(M_{11} + M_{22} + M_{33} + M_{44} + 2M_{12} + 2M_{13} + 2M_{14} + 2M_{23} + 2M_{24} + 2M_{34})$$

It can therefore, be generalized that the bits'-carrying capacity of a switched LAN having n switches, is given by (10). This equation is referred to in this article as the, Eyinagho-Falaki formula for computing any, n -switch LAN's bits'-carrying capacity.

$$CP_n = \mu \left(\sum_{i=1}^n M_{ii} + 2 \sum_{i=1}^{n-1} \sum_{j=i+1}^n M_{ij} \right) \quad (10)$$

Where, n = number of switches in the LAN; μ = the LAN's bottleneck (that is, smallest) link or bits'-pipe's bandwidth (bits/second); M_{ii} = the maximum delay of any bit in switch i ; M_{ij} = end-to-end maximum delay of a bit in origin-destination path $i \rightarrow j$. Furthermore, assume that the switched LAN is connected to the Internet through switch 1 (recall the illustration of Figure 1); designate this switch as the 'Node for Internet Access', which could be a router or layer 3-switch. In order words, traffic with origins in the Internet, which are destined for hosts in the switched LAN, via other switches (nodes), also in the LAN, must all pass through switch 1. Another name for switch 1 in the context of connecting the switched LAN to the Internet therefore, is, backbone switch. In this context, (10) can be re-written in the form indicated as (11).

$$CP_n = \mu \left(\sum_{i=1}^n M_{ii} + 2 \sum_{j=2}^n M_{1j} + 2 \sum_{i=2}^{n-1} \sum_{j=i+1}^n M_{ij} \right) \quad (11)$$

Very useful physical interpretations can be associated with (10) and (11). The component $2\mu \sum_{i=1}^{n-1} \sum_{j=i+1}^n M_{ij}$ of these equations is largely similar to the widely known definition of a bits'-pipe's capacity, which was previously given in this paper. However, all the origin-destination paths' end-to-end delays of switched LANs, which, traverses the n-interconnected switches have been well accommodated by (10) and (11). The total capacity (in bits) of the paths connecting the: 'Node for Internet Access' to the other nodes of the LAN is given by the second component of (11). Therefore, the minimum capacity (in bits) subscription for Internet access is given by (12). See (2) for the case of a single link or bits'-pipe. Let this minimum capacity be denoted as, MinCap-For-Internet-Access (MCFIA), then,

$$MCFIA = 2\mu \sum_{j=2}^n M_{1j} \quad (12)$$

Approach or approaches for determining the bits'-carrying capacities of switched LANs to the best of the knowledge of the research team for this work, seems not to be available in literature; therefore, literature benchmark(s) for making comparisons are lacking. But to directly prove a proposition (that is, a statement that has a true value – which can, either be TRUE or FALSE), or, an assertion of the form $P \Rightarrow Q$ (Q implies P), involves directly arguing that Q is true, and therefore, P is true (Gross & Yellen, 2006, pp. 681-682; Haggarty, 2002, p. 21). This has been done by the arguments that followed (8) and (9). Moreover, (10), (11), and (12) are proposed, closed-form formulas that are solutions to the problem connected with determining the bits'-carrying capacities of switched LANs, and have no basis for simulation.

One important issue that may pop up after going through this paper, is, the applicability of the formulas that are reported; that is, (10), (11), and (12) to Virtual LANs (VLANs), in the context of computing the bits'-carrying capacities of this class of LANs. The answer to this question is not very difficult. It is a well, known fact that, VLANs are logical structures; which implies that, they are physically wired switched LANs, but, logically configured by software as VLANs. The physical configuration of a switched LAN is therefore, not changed by being logically configured as a VLAN. The logical configuration only creates broadcast domains, that is, it (VLAN) groups stations belonging to one or more physical LANs into broadcast domains. Put differently, when a physically- wired switched LAN is configured as a VLAN, the physical (bits-carrying) capacity does not change: this is because, the number of physical hosts or stations, and physical switches, does not change, so also, is the physical wiring, which is not changed. Therefore, the practical utility of the formulas is not changed by the fact that, a switched LAN is configured as a VLAN or not.

An Example to Illustrate the Computation of the Bits'-Carrying Capacity of a Switched LAN

Covenant University, Nigeria, College of Science and Technology (CST) building, switched LAN is used to illustrate the applicability of (10) and (12). It is shown in Figure 3. The LAN has eight switches and

one router. One of the switches (CISCO 3550) is serving as a backbone switch to six other CISCO 2950 switches. A seventh CISCO 2950 switch connects the CISCO 2600 router and the CISCO 3550 switch. It looks like the seventh switch – CISCO 2950 is redundant. There is a DVB (Digital Video Broadcasting) device, used for digital video signals' reception. The CISCO 2600 (which is a router) connects to the VSAT (Very Small Aperture Terminal) through a Radyme Comstream modem. The end-users' hosts or stations that are located in the CST building are interconnected using the CISCO 2950 switches.

Figure 3.

Figure 3 was drawn with the attached hosts not included in the drawing. This is in consonance with the fact that, as was shown by Eyinagho, Falaki, and Atayero (2011), the number of end-to-end delays of a switched LAN only depends on the number of switches in the LAN. It should also be noted that, a router is a switching device, which, in the context of this switched LAN, is taken as one of the switches. Figure 4 shows Figure 3 redrawn, with the DVB receiver, the modem and the VSAT terminal omitted.

Take, $D_{2950\max}$ = the maximum delay of an Ethernet packet in the CISCO 2950 switch, $D_{3550\max}$ = the maximum delay of an Ethernet packet in the CISCO 3550 switch, and $D_{2600\max}$ = the maximum delay of an Ethernet packet in the CISCO 2600 router; it was shown in (Eyinagho, Falaki, & Atayero, 2012, pp.169-171) that, $D_{2950\max} = 41.91945\text{ms} \cong_{42\text{ms}}$, $D_{3550\max} = 41.92\text{ms} \cong 42\text{ms}$, $D_{2600\max} = 41.89\text{ms} \cong 42\text{ms}$. As there are nine (9) switches in the LAN, (10) now becomes,

$$CP_9 = \mu \times \left(\sum_{i=1}^9 M_{ii} + 2 \sum_{i=1}^{9-1} \sum_{j=i+1}^9 M_{ij} \right) = \mu \times ([M_{11} + M_{22} + M_{33} + M_{44} + M_{55} + M_{66} + M_{77} + M_{88} + M_{99}] +$$

[illegible]

Figure 4.

Minimum Bits Capacity Subscription for Internet Access' Computation

Bits' capacities are usually offered by ISPs to their customers in units such as Megabits (Mb), Gigabits (Gb). The computation of this capacity can be performed with Eq. (12). For this switched LAN, $n=9$, therefore,

$$\text{MCFIA (MinCap-For-Inter-Access)} = 2\mu \sum_{j=2}^n M_{1j} = 2 \times \mu \times \sum_{j=2}^9 M_{1j}$$

$$= 2 \times \mu \times [M_{12} + M_{13} + M_{14} + M_{15} + M_{16} + M_{17} + M_{18} + M_{19}] = 2 \times 10 \times 10^6 \text{ bps} \times [84 + 126 + 168 + 168 + 168 + 168 + 168 + 168] \text{ ms} \\ = 20 \times 10^6 \text{ bps} \times 1218 \text{ ms} = 20 \times 10^6 \text{ bps} \times 1.218 \text{ secs} = 24,360,000 \text{ bits} = 24.36 \text{ Mbits.}$$

This is the minimum (and hence, optimum) upload and download, bits' capacity which, for seamless Internet access, is recommended for purchase from an ISP in order for the users whose hosts are connected to this switched LAN to have good QoE (Quality of Experience), during upload and download of information to and from, the Internet. Purchasing above this bits' capacity is obviously a waste of financial resources, except of course, there is an increase in the number of hosts (as a result of increase in the user-base), necessitating the installation of more switches. Purchasing below this capacity will lead to increases in delay, during Internet upload and download sessions, resulting in poor users' QoE.

FUTURE RESEARCH DIRECTIONS

It is proposed here that, utilizing the formulas reported in this article for computing the bits'-carrying capacities of switched LANs, and, the capacities to be subscribed for, when switched LANs are to be connected to the networks of ISPs for the purposes of Internet accesses, presents economic and QoE advantages, over, rule-of-thumb approaches. Further research efforts will now be geared towards carrying out studies to test this proposition.

CONCLUSION

The development of empirical formulas for computing the bits'-carrying capacities of switched LANs, and the bits' capacities, in, for example, Mega-Bytes, Giga-Bytes, to be subscribed for, if there is the need to connect such LANs to the Internet has been reported in this article. Applying any of the formulas is quite simple, requiring mainly, the computation of all the maximum end-to-end delays of a switched LAN. This can be done using, methodologies and formulas which were developed and reported in previous works, as cited in this article. The formulas are in the main, quite novel, as, to the best of the knowledge of the researchers involved in this work, no such practically, utilizable formulas seems to exist in literature. Based on this fact, the researchers resorted to proving, using simple inductive principles, but with quite understandable, physical interpretations, the practical and advantageous utility of the reported formulas.

KEY TERMS AND DEFINITIONS

Bandwidth Delay Product (BDP): This is the product of the Round-Trip Time (RTT) of a link and its bits'-transmission capacity.

Bits'-Carrying Capacity: The maximum number of bits that a network can accommodate at any point in time, without, an abnormal increase in response time, and, decrease in throughput.

End-to-End Delay: This is the time taken for a bit or packet to traverse from a transmitter to a receiver.

Network Performance Management System: An application program that is used to, manage the performance of a communication network.

Node for Internet Access: The router or layer-3 switch that connects an organization's switched Local Area Network to the world-wide Internet.

Round-Trip Time (RTT): This is the time taken by a bit to traverse from a transmitter to a receiver, and back to the transmitter.

Switched Local Area Network: A Local Area Network with the users' hosts interconnected by switching devices, like, switches and routers.

Design and Analysis of AWG and FDL-Based Optical Switch in Data Centre Network

INTRODUCTION

The fast growth in modern computing applications such as video on demand, multimedia application use of the internet of things generates thousands of discrete data in every minute. This rapid growth of data generation, generates a heavy workload on the data center servers. Major content provider companies such as yahoo, google, Microsoft, amazon, etc, has installed mega data center systems which house hundreds of thousands of servers in large scale layouts. (Habib, 2012; Koley, 2010; Katz, 2009). In the network as the demand of network services increases the requirement of high bandwidth also increases. The electronic devices do not fulfil this demand of higher bandwidth because of speed constraints (Sato and Hasegawa, 2009). So, the use of optical technology plays a significant role. Now days to meet this increasing demand in communication network the optical network technologies are explored by researchers. The one of the promising techniques is an optical packet switched network. In an optical packet switching system all switching functions are performed optically. The optical network system consists of core and client networks. In optical switching system, this is difficult to implement the control and processing units in optical domains and this is not technical feasible. So, in most of the optical switching system, the buffering and switching are performed optically while all the control functions are performed in electronic domain.

The main objective of this article is to discuss a wavelength division multiplexed, optical switch. The physical layer and network layer analysis of switch is presented in the article. The switch is placed in to the network and the overall performance of switch is measured under different conditions when it is placed in to the network.

BACKGROUND

In this section a brief background of optical network is presented the various devices which are used in to the core of optical switches is also discussed in this section.

DOI: 10.4018/978-1-7998-3479-3.ch068

Advantages of Optical Communication

The optical fiber technology is based on the propagation of the optical pulses in optical fiber. Hence, the system offers advantages like large optical bandwidth (theoretically infinite), shock proof immune to interference etc. The advantages of the optical fiber communication can be summarized as (Agrawal, 2012):

1. The optical fiber cable offers a very large bandwidth, it is very light weight, and diameter is very small, hence laying of cable is not a daunting task.
2. The optical fiber cable is non-conductor; hence systems are shock free.
3. The optical fibre systems are immune to Interference and Crosstalk
4. The transmission is very secure and fiber lay down under ground and tapping of the signal is not possible. Thus, it offers very high security of signals.
5. In the region of interest the transmission loss is negligible.
6. The optical fiber communication systems are rugged and very flexible.
7. The optical fiber communication systems are very reliable and maintenance is easy.

GENERIC OPTICAL FIBER COMMUNICATION SYSTEM

In 1960, during his research for US Air force, RAND corporation scientist Paul Baran was the first one to introduce the concept of packet switching in 1960 (Agrawal, 2012). In packet switching, the information is transferred into small size packets. Each packet contains small chunks of data which is to be transmitted between various nodes into network. Inside the network, at each node the packets are either buffered or it can be directly transmitted towards the output port which results into variable queuing delay among packets. This feature makes a difference between circuit and packet switching as in circuit switching a dedicated path is established in advance and continue till communication takes place. For optimizing available network channel capacity, packet switching technologies are used (Agrawal, 2012). By using packet switching, the transmission latency can be minimized (i.e. the time taken by data to pass across the network), and the robustness of network can be increases (Koch, 2012).

Figure 1. The generic optical fiber communication system.

Optical packet switching (OPS) is a switching technology with fine granularity. OPS technology transmits data in optical domain without O/E and E/O conversion (Koch, 2012). The key issue involved in the OPS is the design of the switch/router which can perform switching of the data at a very high data rate. In this article, design and analysis of AWG based optical packet switch is detailed with its advantages and limitations. The performance evaluation of the switch is done at both physical and network layer.

The generic optical fiber communication system is shown in figure.1. The information is generated in the form of an electrical signal, generally derived from a real message signal which may or may not be electrical (e.g. sound), to a transmitter comprising electrical and electronic components which converts the signal into an appropriate signal format for propagation over the transmission medium. The optical carrier generally modulated with electrical and optical modulator. On the other hand, at the receiver the optical signal is again converted back into the electrical signals and directed towards destination (Habib et al., 2012). The above depicted figure 1 only shows a single fiber link, between the source and destination. However, in networks thousands of such links exist. A simple optical network layout is discussed in next section.

OPTICAL NETWORKS

The figure 2 shows the generic layout of network. The network structure contains the client and the core networks. In between client and core network the edge routers are used as an interface. These edge router lies on the periphery of the network cloud.

Figure 2. The generic layout of the OPS system.

In network currently both core and edge routers are electronic in nature. The major drawback of electronic switches/routers is that it has limited speed (Tucker, 2008). Therefore, in high data rate transmission the use of electronic routers is not feasible. This inadequacy of the electronic routers gives rise to birth of optical networks. The major issue involved in the design of optical networking is the design of the switch routers which can perform efficiently in the high data rate network. These can be classified as

‘all’ - optical or photonic switches (Tucker, 2008). In first category i.e. in all optical mode, both the data propagation and processing are performed in optical domain. In current industry due to the unavailability of optical RAM all optical switches are not technically feasible (Tucker, 2008). In the other mode the data transmission is performed in optical domain while the control operations are performed in electronic domain. By using photonic packet switching in network, high speed transmission, format transparency efficiency and flexibility in the configuration is achieved. In next generation telecommunication system, the edge routers work in electronic domain and the core routers will be implemented optically. This hybrid approach allows the efficient utilization of the mature electronic technology and huge bandwidth of the fiber in optical domain. In this approach, it is assumed that edge routers are capable of packet aggregation; means they can handle variable length packets arriving from the various client networks. Finally, edge routers push the fixed length packets in the core routers networks.

TRANSMISSION TECHNOLOGIES

In optical transmission two switching technologies, optical packet switching and optical burst switching are heavily investigated in past (Yoo, 2006; Xuy, Perros and Rouskas, 2001; Mujherjee, nd; Stern and Bala 1999; Senior, 2004). In optical burst switching system data units are transferred in to the form of burst of packets while in optical packet switching system the data transmission is performed in the form of small size of packets of same or variable length. The detailed discussion of optical packet switch technologies is as given below:

Optical Packet Switching

In 1960, during his research for US Air force, RAND corporation scientist Paul Baran was the first one to introduce the concept of packet switching in 1960. In packet switching, the information is transferred into small size packets. Each packet contains small chunks of data which is to be transmitted between various nodes into network. Inside the network, at each node the packets are either buffered or it can be transmitted towards the output port directly which results into variable queuing delay among packets. This feature makes a difference between circuit and packet switching as in circuit switching a dedicated path is formed in advance and continue till communication occurs. For optimizing available network channel capacity, packet switching technologies are used. By using packet switching, the transmission latency can be minimized, and the robustness of network can be increases.

Optical packet switching (OPS) is a switching technology with fine granularity. OPS technology transits data in optical domain without O/E and E/O conversion (Yoo, 2006; Xu, Perros and Rouskas, 2001). The key issue involved in the OPS is the design of the switch/router which can perform switching of the data at a very high data rate. In this thesis, design and analysis of AWG based optical packet switch is detailed with its advantages and limitations. The performance evaluation of the switch is done at both physical and network layer.

OPTICAL SWITCH DESIGN AND COMPONENTS

In the design of the optical switch or networks various optical components are needed. Over, here only those components are discussed which are used in the work presented in the article.

Splitters and Combiners

The generic layout of splitter and combiner is shown in figure 3. The splitter is a device which is used to divide the power of incoming signal in equal parts whereas on the other hand, the combiner is used for the opposite. The splitter and combiners are wavelength insensitive devices.

Figure 3. Schematic of Splitter and Combiner.

Multiplexer and De-multiplexer

For combining and separating light signals at different wavelength, MUX and DEMUX are used in optical devices. These two devices are used as wavelength sensitive devices. In general, WDM MUX/DEMU are based on arrayed waveguide grating or interferometric principle. The figure 4 shows the design of Mux and Dmux.

Figure 4. Schematic of Multiplexer and Demultiplexer.

Arrayed Waveguide Gratings (AWG)

The AWG router is used to map an input waveguide to an array of output waveguides in such a way that the different wavelength signals present in the input waveguide are mapped on the different output waveguides (Kato, et al., 2000). The AWG works on the interferometer phenomenon. In wavelength division multiplexing optical systems, they are used as optical multiplexers/ demultiplexers. The figure 5 shows the design of AWG router. The arrayed waveguide grating router follows a definite routing pattern of different wavelengths. The figure 6 shows a routing pattern of 4×4 AWG.

Figure 5. Representation of Arrayed Waveguide Grating.

Figure 6. Representation of routing pattern of 4×4 AWG router.

Routing Pattern		Outputs			
		1	2	3	4
Inputs	1	λ_1	λ_2	λ_3	λ_4
	2	λ_2	λ_3	λ_4	λ_1
	3	λ_3	λ_4	λ_1	λ_2
	4	λ_4	λ_1	λ_2	λ_3

Tunable Wavelength Converter (TWC)

The invention provides a tunable wavelength converter that converts an optical signal from one wavelength to another set of wavelengths as shown in figure 7. In general wavelength converters are expected to have the following features:

1. Large wavelength conversion capacity
2. Fast wavelength tuning time
3. Polarization independent
4. High Signal to noise ratio.
5. Transparency to bit rates and signal formats.

Figure 7. Design of Tunable Wavelength Converter

Optical Amplifier

Optical Amplifier is a device which is used to amplify the optical signal directly without converting it into an electrical signal. In general, two types of optical amplifiers are used commonly.

Semiconductor Optical Amplifier

Semiconductor Optical Amplifier (SOA) is a type of amplifier which is used to amplify the optical signals into optical domain. The gain and noise factors in the case of SOA are represented as:

The gain and noise factor in semiconductor optical amplifier are modelled as:

$$G = G_0 \exp \left(- (G - 1) \frac{P_{in}}{P_{sat}} \right)$$

$$S_{sp} = \eta_{sp} h\nu (G - 1) \text{ Watts/Hz}$$

In this equation, G represents SOA gain, G_0 is used to represent unsaturated gain, P_{in} represents the input power enters in to SOA, P_{sat} shows saturation power level, S_{sp} represents amplifier spontaneous emission (ASE) noise power spectral density, n_{sp} represents spontaneous emission factor, h is Plank's constant and ν represents optical frequency.

EDFA (Erbium Doped Fiber Amplifier)

In the case of long range optical fiber communication, EDFA is the most important amplifier. By using EDFA, we can efficiently amplify the light signal in 1.5 μm wavelength region, where telecom fiber has the minimum loss (Ramaswami, Sivarajan and Sasaki, 2009). As like in SOA, the EDFA amplify the optical signals into the optical domain so that there is no need of expensive O/E and E/O convertors. The figure 8 shows the generic layout of EDFA. The table 1 shows the difference between both amplifiers' SOA and EDFA.

A piece of fiber is used in EDFA, whose core is doped with Erbium ions.

Advantages of EDFA

1. High Gain
2. Low Noise
3. Low temperature sensitive
4. Excellent Coupling

Disadvantages of EDFA

1. Pump laser is required
2. Integration with different components is difficult
3. Dynamic control is required

Figure 8. Schematic diagram of EDFA.

Table 1. Difference between EDFA and SOA.

Property	EDFA	SOA
Gain (dB)	>40	>30
Wavelength	1530-1560	1280-1650
Noise Figure	5	8
Size	Rack Mounted	Compact
Cost Factor	Medium	Low
Switchable	No	Yes

SOME PROMINENT AWG BASED OPTICAL SWITCH DESIGNS

In this section some recently published AWG based optical packet switch architectures are discussed in brief.

In 2013 the H. Rastegarfar (2012) presents an AWG based optical packet switch architecture the switch is a recirculating loop buffer-based switch. In this design when packet arrives at the input of switch the TWC present at the input converts the wavelengths of incoming packets as per the routing pattern of AWG. Here if the packet feels contention then it is forwarded towards the recirculating loop buffer where packets can be stored. After one circulation if the packet still feels contention then it is again forwarded towards the direction of loop buffer other wise it is forwarded towards the output port of switch.

In 2013 Y. Yin et.al. (2012) proposed a buffer less NACK based optical switch design in which due to absence of effective buffering mechanism a large number of packets will be re-transmitted. In 2017 P. Bhattacharya et.al (2017) proposed a design having a $N \times N$ AWG router and N input / output lines used as the core of switch. The data receives at the input lines are in the form of packets. In design each input is connected with a TWC which tunes the wavelength of incoming packets as per the routing pattern of AWG.

In 2018 A. Singh et.al. (2018) proposed a switch design. This switch uses a hybrid optical buffer that merge the advantages of both fast-electronic buffering and fiber optical buffering. In this design numerous sets of fiber loops and electronic buffering modules are joined and develop the hybrid optical buffer. Initially the packets are stored in to the optical buffer, in a temporarily basis. In the event that packet cannot be sent out after a particular interval, the conversion of packet will be done and it will be stored in electronic memory.

ARCHITECTURE DESCRIPTION AND PROPOSED MODIFICATIONS

In figure 9 an AWG based switch is presented in which fiber delay lines are used as an optical storage (Shukla and Srivastava, 2015). The whole switch is divided in to two sections scheduling and switching sections. The control operations in the switch are performed through electronic controller and data transmission is performed optically. In the scheduling section of switch, at input a set of TWC is present which is used to convert the wavelength of incoming packets as per the routing pattern of first AWG. The first N ports of scheduling AWG are linked with fiber delay lines these delay lines are used to store the contended packets. The other $N+1$ to $2N$ ports are worked as actual input-output port of the architecture. In switching section, a set of TWC is present just after first AWG these TWC are used to convert

Figure 9. Schematic of AWG based switch design (D1) (Singh & Srivastava, 2018).

the wavelength of incoming packets as per the routing pattern of switching section AWG and at last the switching section AWG forwarded the packets towards its appropriate destination port. The total number of buffer modules present in the switch are “ m ” and it is to note that the maximum value of “ m ” is N .

Problems in Switch D1

Some of the major Problems associated with the architecture D1 are as follows:

- The buffered packet has the poor quality of signals in comparison to the direct transferred packets.
- As the length of each buffer unit is different so buffer packet also suffers different loss.
- The optimum receiver design is not possible, as different packet suffers different loss.

Due to the problems associated with the architecture D1, there is a need to modify the switch architecture. Hence, modification in the design of switch is proposed and the performance in terms of loss, power and cost are presented in to the paper.

Architecture Modifications

In modification an SOA is placed at each input branch of scheduling section AWG as shown in figure 10. Here the loss of the loop as well as directly transferred packets are fully compensated by the corresponding amplifier available at each input of switch. The advantage of this modification is that, SOA is a noisy device and some of noise generated by SOA are reduced by other components.

The figure 10 shows a modified architecture this modification makes sure that each of the packet have same optical power once they received at the output of switch. Otherwise some of the packets have better signal quality in comparison to others, and it may happen that some of the packets may not have sufficient power that can be detected at the output of switch.

Figure 10. Schematic of AWG based switch design (D2) (Srivastava & Singh, 2010).

ANALYSIS OF SWITCH D2

In this section the detailed loss, power analysis of switch D2 (figure 4) is presented.

Case1: Loss analysis of switch D2 when packet passes through the buffer

The total loss of switch D2 when packet passes through the buffer is given by eq. (1):

$$A_T = A_{TWC} A_{SOA} A_{FDL} A_{AWG}^{2N \times 2N} A_{TWC} A_{AWG}^{N \times N} A_{AWG}^{2N \times 2N} \quad (1)$$

Case2: Loss analysis of switch D2 when packet directly passes through the output unit

The total loss of switch D2 when packet directly passes through the output unit is given by eq. (2):

$$A_T = A_{TWC} A_{SOA} A_{AWG}^{2N \times 2N} A_{TWC} A_{AWG}^{2N \times 2N} \quad (2)$$

Power Analysis of Switch D2

Power entering in buffer module for bit b is given by eq. (3)

$$P_s = bP_{in} \quad b \in [0,1] \quad (3)$$

Power at the output of the switch D2 is given by eq. (4)

$$P_{out}^{D2} = P_{in} + n_{sp}(G-1)h\nu B_0 A_{TWC} A_{AWG}^{N \times N} A_{TWC} \quad (4)$$

Noise Analysis of Switch D2

At receiver, different noise components for the bit “b” are presented through the set of eq. (5):

Shot noise

$$\sigma_s^2 = 2qRPB_e$$

ASE-ASE beat noise

$$\sigma_{sp-sp}^2 = 2R^2P_{sp}(2B_o - B_e)\frac{B_e}{B_0^2}$$

Sig-ASE beat noise

$$\sigma_{sig-sp}^2 = 4R^2P\frac{P_{sp}B_e}{B_0}$$

Shot-ASE beat noise

$$\sigma_{s-sp}^2 = 2qRP_{sp}B_e$$

Thermal noise

$$\sigma_{th}^2 = \frac{4K_BTB_e}{R_L} \quad (5)$$

The various noise components will be given by eq. (5), the expression for P and P_{sp} will be given by eq. 6-7

$$P = bP_{in} \quad (6)$$

$$P_{sp} = P_{in} + n_{sp}(G-1)h\nu B_0 A_{TWC} A_{AWG}^{N \times N} A_{TWC} \quad (7)$$

The total noise variance for bit b is given by eq. (8)

$$\sigma^2(b) = \sigma_s^2 + \sigma_{sp-sp}^2 + \sigma_{sp-sig}^2 + \sigma_{s-sp}^2 + \sigma_{th}^2 \quad (8)$$

The BER can be obtained from eq. (9-10)

$$BER = Q\left(\frac{I(1) - I(0)}{\sigma(1) - \sigma(0)}\right) \quad (9)$$

$$Q(z) = \frac{1}{\sqrt{2\pi}} \int_z^{\infty} e^{-\frac{z^2}{2}} dz \quad (10)$$

CALCULATIONS

The table 1 shows the different components and their values used in the calculation.

Table 2. Used parameters and their values (Srivastava, Singh, & Singh, 2008; Shukla, Sonkar, & Srivastava, 2019).

Parameter	Value
Switch Size (N)	4,8
Population inversion factor (n_{sp})	1.2
Amplifier gain (G)	20 dB
Speed of light (c)	$3 \times 10^8 \text{ m / s}$
Refractive index of fiber (n)	1.55
Responsively (R)	1.28 A/W
Electronic charge (e)	$1.6 \times 10^{-19} \text{ C}$
Electrical bandwidth (B_e)	20GHz
Optical bandwidth (B_0)	40GHz
TWC insertion loss (L_{TWC})	2.0 dB
Loss of Scheduling and Switching AWG $L_{AWG}^{2N \times 2N}$	3.0 dB
Loss of the fiber loop (L_{FDL})	0.2 dB/km
Loss of SOA (L_{SOA})	1 dB

Loss of the Architecture D2

Inserting the values of the various loss parameters we get the total loss of switch as shown in eq. (11-12),

When packet passes through buffer

$$A_b^T = 15.6 \text{ dB} \quad (11)$$

For straight through packets

$$A_r^S (\text{dB}) = 11.0 \text{ dB} \quad (12)$$

Here eq. (11) represents the loss through the buffer and eq. (12) straight path loss in switch D4. It is obvious that the loss in both the architecture is same due to the same number of components. However, in this switch each packet is passes through SOA so in each case when packet passes through buffer or straight through loss are compensated through SOA as shown in eq. (13).

$$A_r G_{\text{SOA}} = 1 \quad (13)$$

The total loss of the switch D2 is given by eq. (14)

$$A_r = 0 \text{ dB} \quad (14)$$

However, the noise value of each switch will be different as the position of SOA in both the architecture is different.

PERFORMANCE OF SWITCH IN TO THE NETWORK

In the previous sections the performance of switch is measured as an isolated switch. In this section the overall performance of switch is considered when it is placed in to the network where cascading of multiple switches is required. Figure 11 shows the structure of switch when it is placed in to the network where multiplexed data traverses from one node to other. The multiplexed data will arrive at the switch input then first the input data is first demultiplexed however, as the data can arrive at any wavelength range, splitter should be used at the input, and combiner at the switch output. The structure of switch is presented as in figure 12.

THE LOSS ANALYSIS

The loss analysis of switch when packet passes through the longest FDL of buffer. The splitter and combiner both are lossy devices and their insertion loss is high in comparison to other devices so use of splitter and combiner increases the overall loss of the switch. The overall loss of switch is calculated as follows by equation (15).

Figure 11. Switch design ready to use in the network (D3).

$$L(S) = L_{Splitter} + L_{TWC} + L_{AWG} + L_{FDL} + L_{TWC} + L_{AWG} + L_{SOA} + L_{Combiner} \quad (15)$$

Now putting different loss values the overall loss of the switch is given by eq. (16)

$$L(S) = 12 + 2 + 3 + 1 + 2 + 3 + 1 + 12 = 36dB \quad (16)$$

In above calculation the size of scheduling AWG is considered as 8×8 . Hence when data traverse through the switch, it faces huge insertion loss of 32dB. So, in the network, for compensating this huge loss optical amplifier like EDFA is required. Beyond this, the loss is also minimized by replacing splitter and combiner by Demux and Mux. The combination of Demux and Mux do the same job as splitter and combiner with very less insertion loss. After this replacement the total loss of the switch is given by eq. (17)

$$L(S) = L_{Demux} + L_{TWC} + L_{AWG} + L_{FDL} + L_{TWC} + L_{AWG} + L_{SOA} + L_{Mux} \quad (17)$$

By putting the various loss values the total loss is calculated in eq. (18):

$$L(S) = 2.5 + 2 + 3 + 1 + 2 + 3 + 1 + 2.5 = 17dB \quad (18)$$

After replacing Splitter and combiner by Mux and Demux the new design of switch, ready to use in the network is as shown in the figure 12.

Power Analysis of Switch D4

Using, the analysis as done in previous sections of this paper, power at the output of the switch D4 for bit b is

Figure 12. Switch design ready to use in the network (D4)

$$P_{out} = bP_{in} + n_{sp}(G-1)h\nu B_0 L_{AWG}^{2N \times 2N} L_{TWC} L_{AWG}^{N \times N} L_{MUX} \quad (19)$$

In the previous sections of this paper analysis of an isolated switch design is presented. When switch is placed inside the network switch D4 emerges.

Let us consider a network as shown in the figure 13. The network presented in to the graph has total of 6 nodes in to the networks distances among different nodes are shown through the edges between these nodes. In the directed graph the node 1 is the source node while node 4 acts as the destination node. Now considering the shortest path among source and destination node in the graph the shortest path from source to destination is 1-6-3-4 and shortest distance from source to destination is 1.64 unit.

In general, distances among adjacent nodes in optical core networks are in some hundreds to some thousands of kilometres. Considering 1unit=1000km. So, the total travelled distance in the graph is 1640 km. Let us suppose the loss of the fiber is 0.2dB/km. So, the total calculated loss is 328dB. Suppose EDFA of gain 30dB each are placed in the links of the network. In this case for compensating losses of 328 dB the required numbers of amplifiers are 11 (10 of 30 dB and one of 28 dB). Similarly, we can count the number of amplifiers required for any of the network.

In network, the new equation for power calculation would be given by eq. (20)

$$P_{out} = bP_{in} (L_{in} G_{in})^K + N_{sd} n_{sp} (G-1)h\nu B_0 L_{AWG}^{2N \times 2N} L_{TWC} L_{AWG}^{N \times N} L_{Mux} + K n_{sp} (G_{in} - 1)h\nu B_0 \quad (20)$$

Where, L_{in} and G_{in} are the loss and gain of the inline amplifier, and 'K' is the number of inline amplifiers and N_{sd} is the numbers of switch through which data moves between source to destination. Again, by using equation (20) and choosing the values of different parameters from table 2, BER can be re-evaluated at different power levels.

In the previous sections, from the analysis presented for switch D2 the BER analysis at various power levels is presented in Table 3 to 5 for different switch configurations. BER vs. power is shown as isolated switch in Table 3. It is obvious that as the power increases BER improves. For acceptable $BER \leq 10^{-9}$, the minimum amount of required power is 140 nW which is very less in comparison to the earlier switch

Figure 13. Considered network Digraph.

designs where power requirements are in micro and sub-micro levels. When switch is made compatible with network, the power requirement increases to 160 nW (Table 4).

Table 3. Bit error rate for switch D2 at various power levels.

Power in nW	BER
100	4.38×10^{-7}
110	6.11×10^{-8}
120	8.07×10^{-9}
130	1.01×10^{-9}
140	1.21×10^{-10}
190	1.68×10^{-15}
200	1.62×10^{-16}

Table 4. Bit error rate for switch D3 at various power levels.

Power in nW	BER
120	4.14×10^{-7}
130	7.51×10^{-8}
140	1.30×10^{-8}
150	2.15×10^{-9}
160	3.41×10^{-10}
200	1.51×10^{-13}

Table 5. Bit error rate for switch D4 at various power levels when it is placed in to network.

Power in μW	BER
1.3	3.56×10^{-8}
1.4	9.11×10^{-9}
1.5	2.31×10^{-9}
1.6	5.86×10^{-10}
1.7	1.47×10^{-11}
1.8	3.69×10^{-11}
1.9	9.22×10^{-12}
2.0	2.29×10^{-12}

When switch placed in the network, the power requirement is 1.6 micro-watts (Table 5). This analysis is very meaningful, as in optical technology, 3R regeneration is not possible, and so from the transmitted node packet should be generated with the required amount of power so it can reach its destination.

Table 6. Comparative analysis of switch.

Switch Design	Power
Isolated Switch (D2)	130 nano-watts
Switch ready to place in Network (D3)	160 nano-watts
Switch in the network (D4)	1.6 μW

Table 6, compares the switch design and acceptable power levels. It is obvious from the table that there is huge power difference in different configurations of the switch. It must be remembered that the required amount of power will vary network to network as both distance between source to destination node pair will change and number of hops traverse will also change.

FUTURE RESEARCH DIRECTIONS

The one of the major challenges in the deployment of OPS is that the transferring of packet only in the optical domain without O-E-O conversion is not possible. Electronic packet switching employs input and output buffering to perform store and forward processing needed at each switching node. This is not possible just because the unavailability of optical RAM. Two approaches are commonly used to overcome the lack of optical RAM, we can use fiber delay lines-based buffers that stores packets in to optical domain. The switch discussed in to the article is FDL based switch and it uses fiber delay lines for storing the packets whenever situation of contention among packets arises. The major drawback of using FDL lines are that, this approach significantly increases the complexity of the switch architecture and its control. The extra latency is also introduced in to the system. Moreover, this method affects the signal power and by this method the packets are delayed only for fixed time, so the method does not solve the problem completely. The second approach which is used in the OPS switches are to introduces buffering at the edges of switching network. In this method buffering can be implemented by using the

electronic buffer at the edge while on the other hand switching process is in optical domain. But this method is applicable only in the systems that feature short host switch distances. In fact, in the situation of contention, the packets which are to be stored at the edge of switch needs to be retransmitted. In the present day's optical environment, the researchers are focused in the design of hybrid buffer which contains all the quality features of electronic as well as optical buffering. Some of the switches using hybrid buffer are presented in by P. Nair and Ramesh P.G.V. (2013). This paper presents a scheme for hybrid burst assembly and a hybrid burst loss recovery scheme which selectively employs proactive loss recovery mechanism depending on the classification of traffic into short term and long term, respectively. Traffic prediction is made using the hidden Markov model (HMM). This dynamic hybrid approach based on HMM prediction provides overall a lower blocking probability and delay and more throughput when compared with forward segment redundancy mechanism. Ahmed Nabih et al. (2014) a hybrid optical switch (HOS) based on wavelength division multiplexing and optical code division multiplexing (WDM/OCDM) scheme is detailed. In this optical cross connect (OXC) can control and process requests for both circuit establishment and burst scheduling. The results are presented in terms of the blocking probability, probability of error, and probability of outage. Except these switches the numbers of other switches are also available that uses hybrid buffering techniques. So, from this study we can say that the scope of research in the design of switch are not limited and there are number of possibilities, from this article we can analyse the effect of each optical component on the performance of switch which gives a brief layout of switch design.

CONCLUSION

In this paper the performance analysis of an AWG based switch is presented, this switch is realized by using TWC, AWG and piece of fiber in the core of switch. In this architecture the routing pattern of AWG is considered and its symmetric nature, simplify switch operations significantly. In this paper design modifications are suggested and a comparison between original design and modified designs are performed through physical layer analysis of each switch. The obtained results presented in this paper clearly favour the suggested modifications.

- The total physical loss of modified switch is fully compensated by corresponding SOA presented at each input of switch both buffer and straight through losses are fully compensated by SOA. This makes modification more useful.
- The obtained results presented in this paper clearly reveals that the nano-watt power level is required in the correct operations of switch D2, which is very less in comparison to other switches available in to market.
- In the analysis presented in the paper obtained results clearly reveals that analysis is meaningful in the absence of 3R and when cross-layer optimization is done. It has been found that as in isolated switch power requirement is 140 nano watts which increase to 1.6 microwatts in the considered network.

KEY TERMS AND DEFINITIONS

Amplifier: The amplifiers are the devices which are used to amplify the signals when the signal strength goes down.

AWG: The AWG router is used to map an input waveguide to an array of output waveguides in such a way that the different wavelength signals present in the input waveguide are mapped on the different output waveguides.

BER: As the name implies the bit error rate is defined as the rate at which the error occurs in the transmission medium.

Fiber Delay Lines: The fiber delay lines (FDL) are used in the switch for storing the packets in to the optical domain.

OPS: In optical networks, it is assumed that the data traverse from one node to another node in a form of fixed size packets are referred as optical packet switching (OPS).

RAM: Due to unavailability of optical storage device the RAM is used as the electronic buffer in to the design of switch.

WDM: The wavelength division multiplexing is a technique which modulate the optical carrier signals of varying wavelengths of laser light, onto a single optical fiber.

INTRODUCTION

With the growing demand of electricity, the traditional power transmission grids are unable to manage instant upsurges in the utilization of electricity and thus often lead to blackouts and power outages (Gao, Xiao, Liu, Liang & Cheng, 2012). Smart grid technology (Farhangi, 2010), which is a digital upgradation of the traditional grids, can overcome the above-mentioned issues and thus provides reliable, secure, safe and efficient power distribution and management. A smart grid system is mainly composed of control centers, mobile workforce, substations, utilities and the customer premises (Saputro, Akkaya & Uludag, 2012). A reliable communication link between all these building blocks is the core element that governs the efficiency of the overall system. Some of the extensively used communication networks in this technology are wide area network (WAN), neighborhood area network (NAN) and home area network (HAN) (Saputro et al., 2012). For example, HAN is located in the customer premises and thus provides a connection between the smart meter and the home appliances. These networks and their interrelationships are depicted in Figure 1.

The routing protocols play a vital role in establishing a secure and reliable communication link between the components of the above-mentioned smart grid networks. In this regard, the ZigBee (Kinney et al., 2003) routing protocol is commonly used in wireless HAN and provides a reliable, secure and uninterrupted connection between various components of HAN, i.e., home appliances and the smart meter (Saputro et al., 2012). Conventionally, the analysis of these network protocols is performed using live testing and computer-based simulations (Lundgren, 2002) using network simulators (McCanne, Floyd, Fall & Varadhan, 1997). These techniques can analyze a limited number of possible scenarios and thus there is always a chance of missing a corner case, which compromises the accuracy of the analysis. Moreover, round-off errors due to the involvement of the computer arithmetic also introduce some approximations and thus we cannot certify a complete absence of bugs. Therefore, considering the safety-critical applications of power and electricity in our daily tasks, these inaccurate results may lead to many unwanted consequences.

Formal methods (Hasan & Tahar, 2015) have the ability to overcome these inherent limitations of the above-mentioned conventional techniques. The formal methods based system analysis mainly involves developing mathematical model of the given system based on some logic and verification of its intended properties using deductive reasoning. The involvement of the logical modeling and deductive reasoning enhances the chances of catching subtle errors that are often ignored by the traditional methods. For

Figure 1. Smart grid Communication Network

example, for a 32-input adder, we require $2^{64} = 1.8446744 \times 10^{19}$ test vectors in the case of computer-based simulations and it is checked for a limited number of these test vectors to reduce the number of computational overheads. Thus, there is always a chance of missing a bug due to not using the test vector to catch it. However, in the case of formal methods, we need to develop an implementation and specification of the circuit using some appropriate logic and verify that the implementation meets the

specifications of the underlying system. The two most commonly used formal methods include model checking (Baier & Katoen, 2008) and theorem proving (Harrison, 2009).

Model checking is an automated analysis technique, which involves the state-space based modeling of the underlying system and rigorously verifying its properties specified in an appropriate logic. The discrete-time systems are commonly verified using this technique due to its state-based nature. Moreover, it has been frequently used for analyzing concurrent systems (Clarke, 1986; Gradara, 2007). However, model checking is not very suitable for systems exhibiting the continuous behavior due to its inherent state-space explosion problem (Baier & Katoen, 2008), i.e., the issues related to the limited amount of computer memory and resources for larger systems.

On the other hand, theorem proving is a formal analysis technique, which involves developing a mathematical model of the system to be analyzed in an appropriate logic and verification of the properties of interest using computer based tools known as theorem provers/proof assistants. Based on the decidability or undecidability of the underlying logic, theorem proving can be termed as automated or interactive. Propositional logic is decidable and thus the sentences/formulas expressed in this logic can be verified automatically. However, one of its main limitations is less expressiveness and thus it cannot be utilized for analyzing all sort of systems. Higher-order logic is the most expressive form of logic and it allows modeling and verifying the complex systems exhibiting the continuous behavior. However, due to the undecidable nature, the verification of theorems about sentences expressed in higher-order logic requires a lot of user guidance in an interactive manner.

Due to the involvement of a lot of human interaction, theorem proving is not preferred for the systems exhibiting the discrete-time behavior. However, the automatic nature of model checking along with the suitability for formally analyzing the concurrent systems makes it an ideal candidate for the verification of network and routing protocols. This is one of the major factors for choosing model checking for the formal verification of the ZigBee-based routing protocol for smart grids.

In this chapter, we use the UPPAAL model checker (Behrmann, David & Larsen, 2004) to formally verify the ZigBee protocol for smart grids. The primary motivation for choosing UPPAAL is that it can handle time in its true form (as clock variable) and the fact that it has been used for modeling and the automatic verification of many systems, in particular the network and routing protocols. To illustrate the effectiveness of our idea, we use our UPPAAL model to verify the collision avoidance, bounded liveness and deadlock freeness properties of the smart grids' ZigBee-based protocol.

RELATED WORK

Model checking has been widely used to verify a variety of communication protocols for smart grids. Fehnker et al. (2007) formally verified a light-weight medium access control (LMAC) protocol, which operates in multi-hop energy-constrained wireless sensor networks (WSNs). Through this exercise, the authors mainly detected and resolved the collision between the data packets using UPPAAL model checker. Similarly, a formal modeling and verification of the ad hoc on-demand distance vector (AODV) protocol operating in wireless mesh network (WMN) is presented in Fehnker et al. (2012). The authors used the algebra for wireless networks (AWN) process algebra to model the AODV routing protocol. Next, this AWN model is converted into its equivalent UPPAAL model, which is further used for verifying its properties based on its different dynamic topologies. Hofner et al. used statistical model checker SMC-UPPAAL for the formal quantitative analysis of AODV and dynamic MANET on-demand (DYMO) protocols for WMNs (Hofner & McIver, 2013).

Malik et al. (2013) proposed a framework for the formal analysis of inter control center communications protocol (ICCP) used in exchanging data and control in different control centers. The authors modeled the protocol using an iterative process and verified its safety and critical security properties using the UPPAAL model checker. Similarly, Tschirner et al. (2008) used UPPAAL to verify the quality-of-service (QoS) of biomedical sensor networks (BSNs). The authors mainly verified the network connectivity, packet delivery and deadlock freeness properties using their UPPAAL model. Somappa et al. (2015) provided the verification of the dual-mode adaptive MAC (DMAMAC) protocol, which is used in process control applications. The authors used UPPAAL to formally verify the state-switching and deadlock freeness properties of the DMAMAC protocol. Similarly, Rashid et al. presented the formal analysis of the ZigBee routing protocol using UPPAAL (Rashid, Hasan & Saghar, 2015) for smart grid applications. The context of this book chapter is mainly focused on this work as, to the best of our knowledge, this is the only work that is related to the verification of communication protocols for smart grids.

Kwiatkowska et al. (2002) used probabilistic model checking to formally analyze the IEEE 802.11 wireless local area network (WLAN) protocol using a two step process. The first step involves the construction of a model based on probabilistic timed automaton. In the next step, the property-preserving semantics are used to convert this automaton model into a finite-state Markov decision process, which is verified using the PRISM model checker. Similarly, Ballarini & Miller (2006) used PRISM to formally analyze the sensor-MAC (S-MAC) protocol for WSN with respect to energy consumption and performance.

Fehnker et al. (2009) proposed a framework to analyze the wireless network protocols, which is based on both the simulation and model checking techniques. The authors first modeled the wireless protocol using CaVi, which is a graphical user interface used for the modeling of networks. In the next step, this CaVi model is translated to the Castalia simulator and PRISM models. Finally, the experiments are performed on the simulator to judge the performance of the protocol. Also, the performance properties of the protocol are verified using the PRISM model checker. Similarly, Rossi et al. (2013) presented formal verification and performance analysis of the cognitive wireless networks based on their discrete time Markov chain (DTMC) models using PRISM.

Bhargavan et al. (2002) formally verified the AODV and routing information protocol (RIP) using the SPIN model checker along with the HOL theorem prover. Similarly, Renesse & Aghvami (2004) used SPIN to verify wireless ad-hoc routing protocol (WARP). Islam et al. (2006) formally modeled the dynamic host configuration protocol (DHCP) using process meta language (PROMELA) and formally verified its model using SPIN. A detailed account of the automated formal analysis of routing protocols for WSNs can be found in Chen et al. (2013). Moreover, a survey of the formal analysis of communication network protocols can be found in Qadir & Hasan, (2015).

The area of formal verification of communication network and routing protocols for smart grid systems has not been fully explored yet. There is only a single work reported in the literature, in which the authors presented the formal analysis of the ZigBee routing protocol for smart grids using UPPAAL (Rashid et al., 2015). Therefore, we have chosen to focus on this work in this chapter. Moreover, we have further elaborated the work, which ensures its better understanding to the non-formal methods community and thus addresses a wider audience.

BACKGROUND

In this section, we briefly describe model checking and the UPPAAL model checker to facilitate the understanding of the formal modeling and verification of the ZigBee-based routing protocol presented later in the chapter.

Model Checking

Model checking (Clarke et al., 1999) is one of the major formal techniques, which is commonly used for analyzing concurrent systems, such as network and routing protocols. The model checking-based analysis involves the construction of a state-space model of the given system and specification of the intended properties of the system in temporal logic (Pnueli, 1977), as depicted in Figure 2. Next, both the model and properties are given to the model checker, which explores the state-space exhaustively and automatically verifies the given system based on these properties. In the case of failure of a property, the model checker generates an error-trace, which helps a user to identify and rectify the error found in the system's model. For the larger systems, this technique is subject to the problem of state-space explosion (Baier & Katoen, 2008) caused by the limited availability of computer memory and other computational resources. However, the abstraction of the model or usage of the efficient bounded and symbolic model checking techniques can avoid this problem.

Figure 2. Model Checking

UPPAAL Model Checker

UPPAAL (Behrmann et al., 2004) model checker is extensively used to formally analyze real-time systems. The behavior of the given system is represented as a network of timed automata. The synchronization between each of the individual automaton is done using the phenomenon of channels, which are of two types: namely binary and broadcast synchronization channels. The binary channel is used for synchronizing one automaton with the other, whereas, in the case of broadcast channel, a single automaton is synchronized with all the channels with enabled transitions using *committed locations* in UPPAAL. These modeling and verification features enable UPPAAL as a commonly used tool to formally analyze concurrent systems, such as communication network and routing protocols (Yi, Pettersson & Daniels, 1994).

We can formally verify the UPPAAL model of a system using the properties specified in computational tree logic (CTL) (Orgun & Ma, 1994), which are the formulas in temporal logic and support specifications based on temporal, path and logical operators. The temporal operators involve next (X), always ([]) and eventually (< >). Similarly, the path operators are thereexists (E) and forall (A). Whereas, negation (!), disjunction (||), conjunction (&&) and implication (@) are the logical operators. Table 1 presents the CTL property specification and their graphical representation.

ZIGBEE ROUTING PROTOCOL

ZigBee (Saputro et al., 2012) is a technology, which resides at the top of networking standard IEEE 802.15.4 and is widely used in HANs for smart grids. It exhibits many interesting characteristics, like low power, long battery life and low data rates. These distinguishing features make it a suitable candidate to operate in short range frequencies. In the HAN, ZigBee is mainly responsible for an uninterrupted communication between various smart appliances, i.e., lightings, air conditioner, refrigerator, oven and fans etc. It is build up of four layers that are stacked over each other in the network and include MAC, physical, network and application layers. IEEE 802.15.4 standard is used to define the physical and MAC layers, whereas the application and network layers are based on ZigBee specification (Gomez & Paradells, 2010). ZigBee-based routing protocol uses the master-slave strategy for routing purposes and its architecture is depicted in Figure 3. Here, the ZigBee coordinator is a master and the slaves include various home appliances, i.e., oven, television and refrigerator etc (Hafeez, Kandil, Al-Omar, Landolsi & Al-Ali, 2014). The master (ZigBee coordinator) is mainly responsible for establishing a reliable and uninterrupted communication in the network and thus it directly communicates with all slaves (home appliances) and also manages their intercommunication by coordinating with the home appliances.

The ZigBee-based routing protocol provides the following advantages in HANs:

1. It consumes low power and helps the batteries to last longer for the ZigBee devices present in the network.
2. It helps in avoiding conflicts and collision between different nodes by providing a reliable and highly secured network.
3. It has a very low latency, i.e., about 15ms to 30ms.
4. It has abilities of self-organization in a network (Huq & Islam, 2010).

Table 1. Property Specification in Computational Tree Logic (CTL)

CTL Property	Description	Graphical Representation
$E < > p$	There exists a path where the property p eventually holds	
$A [] p$	p always holds for all the paths	
$E [] p$	There exists a path where p always holds	
$A < > p$	p will eventually hold for all paths	
$P \textcircled{R} q$	Whenever the property p holds q will eventually hold	

Figure 3. Architecture of Zigbee Protocol

FORMAL MODEL FOR ZIGBEE-BASED ROUTING PROTOCOL

The ZigBee-based routing protocol uses the master-slave strategy and thus the main components of its real-time UPPAAL model are the *master* and *slaves* automata modeling the ZigBee coordinator and smart appliances, respectively. The master broadcasts the data to slaves via a wireless channel. Therefore, we require a *medium* automaton that models the channel in our UPPAAL model. The data sending and receiving abilities of a slave are modeled using the *user* automaton. Finally, to model the time bound in the data transmission, we use a *test* automaton, which is later used to verify the bounded liveness property of the underlying system. We consider the following assumptions for our UPPAAL model:

1. Lossless medium for the communication between various components, i.e., every data sent on the channel will surely be received.
2. Two slaves are considered for our UPPAAL model.

The timed automaton corresponding to the master process is depicted in Figure 4. The master automaton initiates the process by sending an enquiry to the first slave, which is represented by the initial transition, i.e., *mas_1* to *mas_2*. The data (enquiry/message) that needs to be transmitted, is modeled by the variable *data* and an enquiry is represented by *data:=0*. Similarly, the update *sla_num:=1* represents the first slave. Now, the channel synchronization *med_free?* is used in the next transition to ensure that the master waits until the data is broadcasted to all the slaves. In the third transition, the broadcasted data from a slave is received by the master. We also specified a condition $t_mas \leq 3$ working as a clock invariant in the master state *mas_3* to ensure that the data is received within 3 time units, which actually models the assumption of the lossless medium. Finally, an increment in the variable *sla_num* in transition from *mas_4* to *mas_2* shows that an enquiry is sent to next slave from the master automaton.

The medium automaton is depicted in Figure 5. The data sent by the master is received by the medium process by synchronizing the input channel *sen_med?* with the master. Next, the medium process broadcasts the received data to all the slaves using the phenomenon of *committed locations*, which enables the broadcast feature for the UPPAAL model. In the case, if a collision is occurred on the medium, the given system will move to *coll_state*.

Figure 4. The Master Automaton

Figure 5. The Medium Automaton

We modeled both the slaves as individual automata, which are almost same, except a couple of different parameters. Figure 6 depicts the automaton for the first slave process. The slave automaton initiates the process from sla1_1 and receives data as a result of synchronization with the medium using input action `rec_med?`, which is represented by the transition from sla1_1 to sla1_2. Now, the slave automaton at location sla1_2 has two possible transitions. The slave either sends an enquiry to the user by transitioning from sla1_2 to sla1_3 or sends a message by transitioning from sla1_2 to sla1_4. For both the cases, the slave will not answer to any user for a couple of time units, which is illustrated by the self-transitions on sla1_3 and sla1_5, respectively.

Figure 6. The First Slave Automaton

A user automaton is modeled for each of the slave processes, which captures the capabilities of data transmission. Figure 7 depicts the first slave's user automaton. It uses the output actions `sen_u1` and `rec_u1` for the data transmission.

We used a test automaton, as depicted in Figure 8, to verify the bounded liveness of the ZigBee protocol. It utilizes a clock variable `t_tes` to express the time bound in the transmission of data. If the transmitted data is not received within a certain time limit, the test automaton will enter into location `sen_failed` for the case when data is not sent within time limit. In the case, if the data is sent successfully and not received then it will be forced into `rec_failed`.

FORMAL VERIFICATION OF ZIGBEE-BASED ROUTING PROTOCOL

As the ZigBee-based routing protocol works on the master-slave architecture, it ensures that there is no collision during the data transmission from master to slaves or one slave to the other slave. Moreover, the sent data should be received within a time limit. Both of these properties authenticate our design and formal model based on UPPAAL model checker. We used the following CTL formula to verify the collision avoidance property:

$$\forall [] (\text{not medium.coll_state})$$

Figure 7. First Slave's User Automaton

Figure 8. UPPAAL Model for Test Automaton

The verification of the above property guarantees that there would be no collision between the master and the slaves over the transmission channel. Next, we verify the bounded liveness property as:

$$\forall [] (T_Autom.sen_failed \vee T_Autom.rec_failed)$$

The verification of the above property certifies that the user-to-user communication delay is bounded. i.e., the system will transmit data within a time limit. Finally, we used the notion of deadlock present in UPPAAL to verify the deadlock freeness of the ZigBee protocol as:

$$\forall [] (\text{not deadlock})$$

Equivalently, the formal verification of this property also ensures the collision avoidance and bounded liveness properties, i.e., the system will never enter in the deadlock states namely `coll_state`, `sen_failed` and `rec_failed` of the master and test automata, respectively. The verification of all the above-mentioned properties ensures the true functional behavior of the smart grids' ZigBee-based routing protocol.

One of the distinguishing features of our formal analysis presented above is that all the state-space is exhaustively explored during the process of verifying the ZigBee protocol. Whereas, in the case of the simulation-based analysis, only some test vectors are explored, which compromise the accuracy of the analysis. Moreover, the verification is done automatically.

CONCLUSION

In this chapter, we presented the formal verification of the ZigBee-based routing protocol, which is widely used in HANs of smart grids to provide secure and reliable connection between the smart meter and home appliances. The UPPAAL model checker was used to model the master-slave architecture of the protocol using real-time automata. We also verified some vital properties of the ZigBee protocol, namely collision avoidance, bounded liveness and deadlock freeness properties, which ensure the correct functioning of the protocol. Our formal analysis of the ZigBee-based routing protocol using UPPAAL illustrates the advantages of using model checking for analyzing smart grid routing protocols.

FUTURE RESEARCH DIRECTIONS

In future, we plan to verify some other routing protocols for smart grid systems, such as wirelessHART (Song et al., 2008) and Z-Wave (Galeev, 2006) routing protocol for HAN. WirelessHART is a secured time-division multiple access (TDMA) based wireless mesh networking technology. Similarly, Z-Wave is used to integrate sensors and actuators and to perform the smart grid HAN services. The other research direction is to use our proposed approach for formally verifying the routing protocols for WAN and NAN for smart grids.

KEY TERMS AND DEFINITIONS

Formal Methods: Formal methods are the computer-based techniques that involve the development of the mathematical model of the given system based on some logic and verification of its intended properties using deductive reasoning.

Home Area Network (HAN): HAN is located in the customer premises and provides a connection between the smart meter and the home appliances.

Model Checking: Model checking is a formal verification method that involves the state-space based modeling of the given system and rigorously verifying its properties specified in an appropriate logic.

Smart Grids: Smart grids are a digital upgradation of the traditional grids providing reliable, secure, safe and efficient power distribution and management.

Timed Automata: Timed automata are the finite automata extended with a set of clock variables and are used for modeling the timing aspects of the system.

UPPAAL Model Checker: UPPAAL model checker involves modeling the behavior of the given system as a network of timed automata and is extensively used for formally analyzing the real-time systems.

Zigbee Routing Protocol: ZigBee routing protocol is commonly used in wireless HAN and provides a reliable, secure and uninterrupted connection between various components of HAN.

QoS Provisioning for Multicast Routing and Channel Assignment in Wireless Mesh Network

INTRODUCTION

Wireless mesh networks (WMN) is defined by a group of nodes which uses a wireless mode of channel and form a mesh topology, where each individual node is connected to the other with a dedicated line of communication. The few distinguished features of WMN's are self-organization, spatial reuse, and fault tolerance. The ad-hoc connectivity enables the WMNs to be of low cost, ease of maintenance, reliability and robustness [Akyildiz et al., 2005]. The scope of development and research in the fields of wireless mesh network is wide open and the focus has been also widened from only effective channel assignment to channel assignment and multicast routing. An effective channel assignment algorithm in WMN maximizes the utilization of network bandwidth. The efficiency of the network performance is generally termed as quality of service (QoS). The main term QoS defines the performance level of a service by the network to the end users. It generally is associated with the behaviour of wireless node or service, throughput sensitiveness and delay sensitiveness in multimedia applications. The QoS provisioning can be simply stated as satisfying a set of network related parameters like jitter, battery life, latency, packet loss ratio and bandwidth. The QoS imparting parameters depends upon the scenario in which it is implemented. In the context of channel assignment the QoS parameters can be signal power, bandwidth, power, etc. on the other hand the QoS parameters for multicast routing are bandwidth, delay, jitter etc. As for voice communication the parameters are battery life, for video communications buffer space, jitter delay, packet loss ratio, for military applications the parameters are strict security parameters. The various real time applications of the day to day life use multicasting such as audio/video conferencing, online gaming, remote learning, webcasting, distance learning, distribution of financial data, billing records, software, newspapers and lots more. WMNs are very much suitable for supporting such type of multicasting application. But provisioning of QoS in multicast routing as well as efficient assignment of channels is a challenging issue. For solving this problem, many techniques have been developed. This chapter presents a detailed study of the QoS provisioning in the channel assignment, multicast routing and both in a network scenario. It also classifies the techniques based on whether it is applied during channel assignment, multicast routing or during both phases. Comparison of the techniques is also presented in a tabular format.

DOI: 10.4018/978-1-7998-3479-3.ch070

BACKGROUND AND CLASSIFICATION

The incorporation of the QoS provisioning in the field of channel assignment and multicast routing techniques is already implemented by a number of techniques. Based on the point where the techniques are applied, QoS provisioning techniques in WMN can be classified in three categories namely, QoS provisioning in channel assignment, QoS provisioning in multicast routing and QoS provisioning jointly in channel assignment and multicast routing. A brief discussion on the already implemented techniques for serving QoS in the channel assignment phase, in multicast routing phase and channel assignment and multicast routing phase has been presented in the joint section.

QoS Provision in Multicast Routing Algorithm

In this section a brief discussion on the techniques for QoS provisioning in multicast routing algorithm has been presented.

Gateway Cluster Based Load Balancing Multicast algorithm

Gateway cluster based Load Balancing Multicast algorithm (GLBM) [Zhao et al., 2010] provides load balancing aware multicast routing algorithm which offers QoS as well as superior performance in terms of delay, jitter and throughput. In this algorithm, the main importance has been laid on the multicast routing communication pattern, since it has a high demand on network bandwidth and also an impact on algorithm execution time. It defines the WMN network in three distinct layers – Internet Gateway layer (IGW), Mesh Router layer (MR) and Mesh Client layer. The algorithm works on the IGW layer and MR layer. As stated above, the algorithm throws light in the concept of load balancing, since the mesh routers is responsible for maintaining the traffic load of the mesh clients. Likewise the gateways maintain the traffic load of the mesh routers and internet. It works as an admin in accessing the backbone internet and maintaining the optimal load balancing. Basically for any multicast routing scheme the lowest hop count route is selected as the best route, but in this scheme the best route is selected in terms of load balancing. The steps in the algorithm are:

- i. Initiating a multicast session – The source node in the multicast group initiates a multicast session to the internet, and sends a Multicast Sender Request (MSR) to its gateway to become a multicast source node. The gateway on receiving the MSR message periodically broadcasts the multicast Hello Message (HM) along with the other routing details like sequence number to other gateway nodes in the network. The gateway node on receiving the HM message, records the backward route to the source node in its multicast routing table and deletes the old entry.
- ii. Receiver joins the multicast session – The receiver which aims at joining in the multicast group sends the Multicast Route Request (MRQ - J) with Join flag and destination IP address to its gateway by broadcasting the request to all the neighbouring nodes at one hop distance. The node receiving this request (MRQ - J) adds the network Interface Queue (IFQ) length to the IFQ aggregation field. The path with the lowest IFQ aggregation is chosen as the multicast path from the gateway to the receiver. The IFQ length determines how busy the network interface of the node is. The gateway checks the multicast routing table. If the IP address is already available in the table then it sends a Multicast Route Reply (MRP) to the request receiver otherwise it sends Multicast Source Reply with Error flag (MSQ-E). The MSQ-E message is to inform the non-existence of the requested multicast session.

- iii. Maintaining multicast session – Whenever the multicast receiver is willing to leave the multicast group, it sends a Multicast Route Request with Leave flag (MRQ-L) message using default multicast route. The gateway node on receiving the MRQ-L deletes the entry of the particular node from its multicast routing table and notifies the multicast source using the Multicast Source Reply with Leave flag (MSQ-L). The multicast source on receiving the MSQ-L message deletes the entry for the receiver node from the multicast routing table and thereby stops sending any further multicast packets to this node.

The algorithm also incorporates the Error repair mechanism. If any receiver r does not receive packets from the multicast source s for a certain period of time, t , the node assumes that the link has broken or s has stopped multicast process. The receiver node r then sends out Multicast Route Request with Repair flag (MRQ-R) to its gateway node. The gateway on receiving the MRQ-R message, checks whether the source node is still forwarding multicast packets or not. If so, it chooses the best load route, updates the route and replies with MRP to the source s , otherwise sends MSQ-E to receiver notifying that multicast session no longer exists.

Hybrid QoS Multicast Framework-Based Protocol

The protocol [Pourfarkhar et al., 2010] combines proactive and reactive multicast routing in order to eliminate unnecessary delays as well as minimize control overhead in setting up routes in backbone mesh network. The main idea is to achieve gateway load balancing in multicast communication of WMN. Cerebral Model Articulation Controller (CMAC) [Albus et al., 1975] neural network model is used for load balancing and traffic oscillation in gateways during QoS multicast routing in WMN. The network model assumed in this protocol has more than one access point. Each multicast session is assigned a multicast group ID i.e. a multicast IP address in order to join or leave the multicast group. Route optimization and load balancing of network are the aims of the proposed protocol. The framework requires neither any knowledge of multicast member's location nor any modification to the existing Internet multicast routing protocol or IP multicast. The paths between the WMN and internet are chosen which guaranty least overloaded AP. The chosen path is backed with minimal delay and congestion. It elevates the packet delivery reliability. The bottleneck nodes can be avoided by distributing the traffic properly and consequently congestion can be controlled. The disconnection emphasis of the APs to the other nodes is higher because of the higher traffic load, so the nodes closer to the APs have more disconnection emphasis than the nodes situated at a distant.

For each node with a distance of h hops to its APs in the network Emphasis Coefficient (E_h) is calculated.

$$E_h = \begin{cases} 3^{h-m} & \text{if } (h < m) \\ 1, & \text{else} \end{cases} \quad (1)$$

If $h = 0$ then $E_h = 3^m$.

The congestion measurement for each node or simply Route Disconnection Expectancy (RDE) between the nodes and its AP with a distance of h hops is calculated as,

$$RDE_h = \sum_{i=0}^h (E_i \times NDP_i) = E_h \times NDP_h + RDE_{h-1} \quad (2)$$

where, NDP denotes Node Disconnection Probability

The path with minimum RDE is the least congested path to the AP with minimum workload. For fast recovery process and to have a load balanced network, each node records characters of another suitable AP as a reserved AP in a separate entry in its routing table along with the main AP. At first AP's are assigned to the mesh routers. The process is stated below,

- i. Each AP in the node announces its presence and status by broadcasting a status-notification messages to all nodes in the mesh at the configuration or reconfiguration time or when its workload increases and its probability of disconnection is high.
- ii. Each node after receiving status-notification messages calculates NDP and adds its RDE in the message packet. Then it records information of the two AP's, main AP and reserved AP in its AP routing table.
- iii. If node receives multiple messages from same AP then one of the neighbours can be chosen as the next node on the path to the AP based on shortest delay (first received message). If the node receives messages from different APs then main AP and reserved AP is selected based on least hop count or least RDE path. If both the nodes has routes with same RDE then choose AP with shortest path or route with minimum hop count is chosen.
- iv. If the selected AP is overloaded the message will be dropped. If a node receives overloaded message from the main AP, then it uses its reserved AP despite using its main AP, until traffic load on its main AP decreases.
- v. Each node after receiving new messages, updates the AP routing table for the main AP and reserved AP entries.

The entire process of assignment of mesh routers to the AP aims at a load balanced network with fast speed recovery, minimum delay routes and routes with minimum congestion.

The Hybrid QoS Multi-cast Routing Framework-Based Protocol for Wireless Mesh Network (HMFPM) supports dynamicity and scalability for wireless networks. The HMFPM works on the following three cases-

- Case I: The sender and receiver is in the same WMN.
 - Case II: The sender is in Internet and a subset of receiver in the WMN.
 - Case III: The sender is in WMN and a subset of receiver in the Internet.
- Case I

1. Before initiating the session, source S unicasts registration request message to its AP through the best route to register the information regarding group G and source S. The AP then broadcasts the information to the other AP in the network.
2. The source S floods the Receiver Discovery (RDS) data packet and buffers subsequent multicast data packet for a short time. All the nodes which receive the RDS packet, forward it and record the previous hop address. When a receiver R receives this packet, it unicasts a Receiver Join (RJN) packet back to S. The nodes which receive and forward the packet towards S, set up themselves as forwarder for this source and group. If a node receiving RJN has a routing table entry for this group and a source indicates that it is a forwarder, then the node will not forward the RJN to the source rather discards it.
3. When a receiver wants to join a group G, it sends a request information message to its AP to ask for the source of group G. The AP then replies with the group information (G, S). If the group is

not a source specific multicast group and there are many source for group G then the AP replies with the group information (G, Init_Val). On receiving the information of the group, if R has a path between it and source S, it unicasts a Join Request (JRQ) packet to S else, floods the network by broadcasting JRQ packet.

4. The intermediary nodes (M) process the received JRQ under three cases –
 - a. If M is neither a member of multicast group nor a forwarder node for source S in G, but has a path to the source S, then it must unicast the JRQ to the source.
 - b. If M is not a forwarder node and has no path to the source S in G, then it must broadcast the JRQ packet in the network.
 - c. If M is a forwarder node in the multicast group G and has received a unicast JRQ, it will not forward the JRQ to source. It creates a Join Reply (JRP) to itself and unicasts it to the neighbour node towards the JRQ sender. If it has received a broadcast JRQ, M only unicasts it to the S.
5. The source S on receiving the JRQ unicasts back a JRP to R.
6. The multicast source S will send the data packets to the forwarding nodes in the multicast group G. Thus the packets are forwarded to the receivers along the shortest delay path through the multicast tree of the multicast group.

Case II

If a receiver R in the WMN wants to join the multicast group G. It sends a request to its AP to ask for the source S of the group. The AP has not yet received any registration message from the sender, it learns that the sender is located outside the WMN. So, it acts as a proxy in the WMN for the Internet Sender. The source AP replies to R in the WMN. All the nodes that receive and forward packet towards R create a forwarding entry in their routing table for source AP and group G and sets the forwarder flag to True. The AP joins the multicast group G in the Internet using the existing Internet multicast routing protocol. On receiving the data packets from the internet sender the AP forwards the packets to the receivers in the WMN using the multicasting tree constructed by the HMFPM protocol.

Case III

The source S sends a message to its main AP to register the group information (G, S) before initiating any multicast session. The AP starts the multicast session in the Internet using the existing Internet multicast routing protocol as if it is the source of group G. After the receiver R in the internet joins the multicast session the AP uses HMFPM protocol to find out the route from source S to itself. The AP on receiving the packet from the sender multicasts it to the receivers in the Internet. The AP joins or leaves the multicast tree in the WMN depending upon the presence of the receivers in the Internet using the HMFPM protocol.

The two main advantages of the HMFPM are:

- Traffic migration – If one gateway stops functioning, the traffic can be routed and handled by another gateway in the WMN.
- Load balancing – Data traffic is distributed among the gateways based upon the associated metrics.

QoS Multicast Routing Algorithm

This technique [Ke et al., 2007] is a multi-constrained QoS based multicast routing algorithm. The network model is presented as a graph G , comprising a set of nodes, V , and a set of duplex links, E , between the node pairs. The goal of this technique is to find an optimal multicast route satisfying the necessary QoS parameters. The optimality conditions considered to select the paths are:

- i. Guaranteed bandwidth requirement,
- ii. End to end delay requirement satisfied,
- iii. Minimal cost.

In this scheme Raidl technique [Raidl et al, 2003] is used to represent the multicast tree. It is spanning tree used for evolutionary search, which compares the multicasting tree with some typical previous coding of spanning tree.

Each node $v \in V$ has a transmission range r . An edge $e(v_1, v_2) \in E$ between two nodes $v_1, v_2 \in V$ exists if distance between them is less than or equal to r .

The QoS parameters are defined as-

- (1) $\text{bandwidth}(t) = \min\{\text{bandwidth}(e(v_i, v_j)), e(v_i, v_j) \in t\}.$
- (2) $\text{Delay}(t) = \sum_{e(v_i, v_j) \in t} \text{delay}(e(v_i, v_j)).$
- (3) $\text{Cost}(t) = \sum_{e(v_i, v_j) \in t} \text{cost}(e(v_i, v_j))$

Here, t is a multicast tree in a set T . T is a set of possible multicast tree in G which connects the source S to every receiver $r_i \in R$. Genetic algorithm is a guided random search and optimization technique based on the basic principles of evolution i.e. survival of the fittest and inheritance. The three important aspects of the genetic algorithm i.e. selection, crossover and mutation are adopted to create individuals of the next generation from the current population.

The multicast tree is created randomly by RandomWalk algorithm. At every step, the algorithm moves over a randomly chosen adjacent edge to one of its neighbours. When all the destinations are found the search stops. The process of selection, crossover and mutation is discussed as follows:

- Selection: For the selection process Roulette wheel selection technique is adopted. This scheme considers the widened number and diverse solutions. The crossover probability P_c is assumed as 0.70 and the cataclysmic probability P_m is assumed as 0.35. It basically employs a heterogeneous recombination and cataclysmic mutation algorithm (CHC) inspired adaptive search [Eshelman et al, 1991] cross-generation selection competition mechanism which guarantees to present the best multicast tree selection. CHC is an evolutionary algorithm with binary coding which tries to avoid premature convergence by getting suitable balance between the ability to explore the search space for diversity and the ability to explore the local properties of the search for an appropriate selection [Luzon et al, 2004].
- Crossover: It is undergone to provide good quality solutions through inheritance from the parent solutions. Two trees are selected from the solution set and RandomWalkMulticastTree(RandomWalkMT) is used to get two off springs.

- **Mutation:** In this sub process a node is chosen randomly from the multicast tree. The edges are dropped which are connected to a node from the neighbouring node. The intersection of adjacencies of the pre-node and next-node of a node are drawn. If the adjacency of both the nodes intersect, then drop the node, else choose a node randomly from the intersection and add the two edges to the multicast tree.

The routing process is inspired by genetic algorithm where the size of the population and number of generation in the population are pre-determined. The initial set of multicast are solutions obtained from the RandomWalkMT. The multicast trees are encoded with the edge-set and different chromosomes are produced. The fitness value of the individuals of the current population is checked by evaluating the fitness function. The individuals of the current population and next population are mixed. Crossover operation is performed followed by mutation over the individuals of the mixed population. The outcomes of the previous steps are evaluated using the fitness function. Considering fitness functions outcome, the best individuals are selected from the mixed population and the current population is generated after the genetic operations. If the current and next population contains the same individuals then cataclysmic mutation is performed to increase the diversity of the solutions. The fitness function comprises of bandwidth parameter and delay cost of the multicast tree.

QoS Multicast Routing Framework

This algorithm [Shittu et al, 2008] addresses the problem of QoS provisioning in multicast routing scenario in WMN. It assumes a working QoS MAC layer protocol and proposes a framework which ensures QoS multicasting at network layer. It uses a combination of proactive or mesh and reactive or tree multicast routing based on backbone mesh routers and client nodes. This approach caters the QoS parameters like delay and congestion of data packets between backbone mesh and client STAs devices. The algorithm takes into consideration a network architecture comprising gateway which is connected to the internet in wired mode. The gateways are multicast sources and are connected to the mesh point in wireless mode. The mesh points act as mesh access points to a group a multicast receivers. The algorithm uses a routing protocol which states that a multicast path is always available before QoS request is done between the backbone mesh routers. This process eliminates the delay in finding the path between the routers. It also in turn minimizes channel access contention problems. The path establishment between the mesh access point (MAP) and end client station (STAs) in multicast group is done after the request is made. The MAP keeps an up-to-date record of link's conditions in the backbone mesh. This process minimizes the routing overheads.

QoS Provision in Channel Assignment Algorithm

In this section a brief discussion on the techniques for QoS provision in channel assignment algorithm has been presented.

Escalating QoS With Channel Assignment and Traffic Scheduling in Wireless Mesh Network

This technique [Salvakumar et al, 2018] uses tabu search heuristic approach for channel assignment in mesh network. The intention is to execute an intelligent exploration of search space that would ultimately get fascinated into local optima.

The two most distinguished features of the Tabu Search method are-

- Adaptive memory that takes intelligent decisions.
- Responsive exploration based on the unsurpassed solution in elongated time run in search space.

For a given explanation s , the neighbourhood of s is denoted by $n(s)$, defined by a set of realistic solution accessible from s by applying.

$$n(s) = \{s' | s' = m(s), m \in M(s), s' \in S\} \quad (3)$$

where, S = Resolution Space.

$M(s)$ = Set of association that can be generated from the solution s .

m = Movement to be applied to s .

The TabuSearchOptimization(TSO) technique is capable of holding memory of all the nodes in the network and assign channel which is interference free, at that particular time t . If there is any external interference in the network the TSO technique suggests the next node in the neighbour nodes for faster transmission of data. The most important feature of TSO technique is memory. The traffic scheduling in this technique is achieved in distributed manner, by sharing of common meta-data links. The traffic scheduling algorithm comprises two processes i.e. CoS quantization of traffic architecture and prioritization of connection request. The CoS quantization of traffic architecture sub process prioritize incoming traffic to guarantee Service Level Agreement. The incoming traffic is classified as:

- i. EF traffic as real traffic
- ii. AF traffic for non-real traffic
- iii. BF traffic for delay tolerant traffic.

The prioritization helps in dropping low priority traffic and identifying the delay tolerant traffic such as file transferring traffic, etc. The next sub process is the prioritization of connection request which is achieved by extracting two parameters from the connection requests- data rate consumption and the number of hops utilized in the network.

The parameters that are catered in the algorithm are hop count, tolerable delay, required data rate, and service priority. The hop count counts for the number of nodes to traverse before reaching the destinations. The tolerable delay is the delay that a connection request can tolerate. It is with reference with the QoS degree accepted at the destination. The minimum data rate required by the connection request throughout the Wireless Mesh Network. The service priority is the classification type of service request that a client is desirous to transmit or not.

Capacity and Interference Aware Link Scheduling with Channel Assignment

This algorithm [Kumar et al, 2011] finds out the traffic flow on each link and assigns the appropriate channel to link for minimizing the interference effect. The problem of channel assignment in this algorithm is formulated using linear programming along with the other related constraints and a new metric named link cost metric (LCM) which is an extension of the metric ETX (Expected Transmission count). In this approach, optimization of channel assignment and link scheduling is done. It also ensures minimum interference. The metric LCM captures the quality of the wireless link. The quality of the link is decided taking into consideration a number of constraints namely, capacity constraint, rate allocation per link, degree constraint and fairness constraint. The capacity constraint ensures that the total traffic passing through the router does not exceed the total capacity of all the channels. The rate allocation per link constraint ensures the minimum rate allocation for active link and maximum allowable time slot per link. The degree constraint checks whether a node is transmitting and receiving at the same time slot. The fairness constraint ensures fairness in traffic distribution. Given a WMN the main goal is to assign each communication link such that number of channels assigned to a particular link should not exceed the limit of radios in a node. The algorithm starts with a link assignment matrix (LAM) where all the group are sorted according to the value of link cost matrix (LCM). The link having the minimum value of LCM is assigned a channel. If there is an interference of links from different groups then assign the channel to the interfering channels. Else select the channel from the channel pool. Sort the interfering links thereby select the link having maximum interference. If there is any priority constraint then assign channel to the link having high priority to avoid further interference. This process is iterated for all the links in all groups of the network. The outcome of the algorithm is a channel assignment matrix (CAM) of the network. The QoS metrics served by this algorithm are – aggregate throughput, packet loss rate, packet delivery fraction (it is defined as ratio the number of packets received to the number of packets transmitted), average end-to-end delay and fairness index.

QoS Provisioning Jointly in Channel Assignment and Multicast Routing Algorithm

In this section a brief discussion on the techniques for QoS provisioning jointly in channel assignment and multicast routing algorithm has been presented.

Quality of Service Channel Assignment and Multicast Routing Algorithm

Quality of Service Channel Assignment and multicast Routing (Q-CAR) algorithm [Chakraborty et al., 2017] is an intelligent solution for joint QoS multicast routing and channel assignment in multichannel multi radio wireless mesh networks. The multicast routing mechanism in multichannel multi radio WMN's has been proved to be a NP-Hard problem. The multicast routing mechanism leads to construction of multicast tree which is a very important unit in multimedia and real time data transfer. It also plays an important role in achieving optimal performance in multi-channel multi radio WMN's scenario. The Q-CAR method solves the multicast tree construction and channel assignment problem conjointly by intelligent differential evolution. Differential evolution is a form of stochastic algorithm for optimization inspired by biological processes which learn from their surrounding environment. The channel assignment algorithm is a slightly modified form of the basic differential evolution approach. The intelligent multicast tree construction phase is based on the genetic algorithm approach. The aim of the scheme is to assign

channels with minimum channel conflict. The fitness of the outcomes of the genetic approach used in the channel assignment algorithm is evaluated using the Signal to noise ratio (SNR) as the fitness measuring parameter, which enhances the overall efficiency. The SNR is the ratio of received signal strength and background noise. The optimization model for channel assignment algorithm is:

$$\text{minimize } f(X_{i,G}) = \frac{1}{SW(T_r) + 1} \quad (4)$$

subject to,

$$\forall r_j \in R_{Tr} \left[\sum_{l_{ik} \in P(s,rj)} \delta_{l_{ik}} \leq \Delta \right]; \delta_{l_{ik}} \geq 0 \quad (5)$$

$$\forall r_j \in R_{Tr} \left[\sum_{l_{ik} \in P(s,rj)} \varepsilon_{l_{ik}} \leq \Delta \right]; \varepsilon_{l_{ik}} \geq 0 \quad (6)$$

Where $SW(T_r)$ is the total signal weight for a routing tree R_{Tr} .

$\delta_{l_{ij}}$ is the average delay experienced at link l_{ij} , $\varepsilon_{l_{ij}}$ is the average jitter experienced at link l_{ij} .

The goal of effectively providing QoS is achieved by subjecting the outcomes of the channel allocation algorithm to the delay and jitter upper bounds. Then the second phase of multicast tree construction is initiated using the outcomes of the previous step i.e. channel allocation. Because it has been seen in the other existing approaches that if the multicast routing outcomes are fed as the input to the channel assignment phase, it causes a major performance degradation. The interference disturbance of the nodes are sensed and the cost of the entire tree constructed is calculated to evaluate the fitness of the units of the genetic algorithm approach (here chromosome).

The optimization model for the multicast routing phase is,

$$\text{maximize } F(Ch_i) = \frac{1}{\beta ID_{Tr} + (1 - \beta) Cost_{Tr}} \quad (7)$$

subject to

$$ID_{Tr} \geq 0, Cost_{Tr} \geq 0; \forall T_r, \beta \in [0, 1]$$

$$\forall r_j \in R_{Tr} \left[\sum_{l_{ik} \in P(s,rj)} \delta_{l_{ik}} \leq \Delta \right]; \delta_{l_{ik}} \geq 0 \quad (8)$$

$$\forall r_j \in R_{Tr} \left[\sum_{l_{ik} \in P(s, r_j)} \varepsilon_{l_{ik}} \leq \Delta \right]; \varepsilon_{l_{ik}} \geq 0 \quad (9)$$

Where, ID_{Tr} is the total interference disturbance on tree T_r . $Cost_{Tr}$ is the tree cost.

The multicast treeconstruction phase is a reactive process, i.e. a multicast tree is built whenever a request for themulticast communication arises. In this method at the generation of the initial popula- tion, thefirst four participating chromosomes are generated using the Prim's algorithm, BFS, DFS and Dijkstra shortest path algorithm in order to speed up the convergence in generating potentialmulticast routing tree. The above mentioned four algorithms generates four candidate solutionshaving minimum interference impact and tree cost, thereby helping in generating better solutionsrather than using random combinations [Chakraborty et al., 2015]. The units of the initial population are succeeded bythe crossover and mutation process thereby generating the entire population of parent population. The most important aspect of the genetic algorithm is the selection of the fittest units to passthem to the next generation depending upon the fitness function. Linear ranking selection schemeis used for selection.

Intelligent Quality of Service Multicast Routing and Channel Assignment Algorithm

The intelligent Quality of service multicast routing and channel Assignment (i-QCA) algorithm [Chakraborty et al., 2015] solvesthe multicast tree construction and channel assignment problem by involving intelligentcomputational methods. This technique involves genetic algorithm for channel as- signment which caters the co-channel conflict for the tree and delay, jitter and minimal interference low cost multicast tree. It basically uses the differential evolution approach in the construction ofthe multi- cast tree and genetic algorithms inspired channel assignment algorithm. The algorithm builds a low cost multicast tree and the QoS determining parameters are delay and jitter bounded minimal interference. It also tries to minimize the total co-channel interference andthe number of the scarce radio interfaces. Here other than the co channel interference the scheme considers radio interfacesbecause in a multicast communication the source has a single radio interface thatsends the multicast packets and the intended receivers deploy one radio interface to receive thepackets. The intermediary nodes perform the both, send and receive. Therefore, the scheme tries to reduce the number radio interface thepacket has to go through before reaching the destination nodes. The optimization model for the channel assignment algorithm is,

$$\text{Maximize } f(Ch_i) = \frac{1}{cc(T_r) + 1} \quad (10)$$

Subject to,

$$cc(T_r) \geq 0; \forall T_r$$

$$\forall r_j \in R_{Tr} \left[\sum_{l_{i \in P(s, r_j)}} \delta_i \leq \Delta \right]; \delta_i \geq 0 \quad (11)$$

$$\forall r_j \in R_{Tr} \left[\sum_{l \in P(s, r_j)} \leq \Delta \right];_i \geq 0 \quad (12)$$

The tree cost is calculated using number of deployed radio interfaces. The fitness function evaluates the quality of a multicast tree in terms of total interference impact and radio interface cost of the multicast routing unit. It is a method which solves the channel assignment and multicast routing in polynomial time.

Quality of Service Multicast Routing and Channel Assignment

The Quality of Service Multicast Routing and Channel Assignment (QoS-MRCA) scheme [Cheng et al., 2011] is concerned with the quality of service multicast routing and channel assignment, thereby giving joint solution for the multicast routing problem. The method includes three algorithms namely genetic algorithm, simple annealing and tabu search to search minimum interference multicast trees which also satisfies the end-to-end delay constraint and optimizes the usage of the scarce radio network resource in the WMN. The above mentioned method aims to build a delay bounded multicast tree and also to minimize total channel conflict. The QoS is provided in terms of both the total channel conflict and the tree cost. The multicast tree cost is used to evaluate the utilization of the network resource as well as treated as a QoS parameter in wireless networks where limited radios and channels are available. The fitness function evaluates the units of multicast routing in terms of total channel conflict and tree cost. This results in choosing a low cost multicast tree on which the minimum interference channel assignment is achieved. The main motive behind the implementation of the method is to improve performance in order to provide QoS to the users in various collaborative multimedia applications which require efficient information delivery service from a designated source to multiple receivers. The genetic algorithm is a stochastic meta-heuristic optimization method that involves methods and model from biological principles of Darwinian Theory of evolution and Mendelian principles of inheritance. The objective function involves minimization of the total channel conflict, in order to improve the system throughput. This scheme uses an effective channel assignment algorithm which gives least channel conflict on any multicast tree. For ease of presentation binary interference model is adopted where two links either totally interfere or don't interfere at all. In the multicast routing, a tree is evaluated with minimal tree cost, as the number of the radio interfaces involved in the multicast communications. In order to reduce the tree cost, the number of links used in the multicast routing tree and the end-to-end delay has been reduced. Regarding the fitness function, the primary criterion regarding solution quality is the total channel conflict and the subsidiary one is the tree cost. Thereby, among the candidate solutions with the same minimum channel conflict, and choosing the one with the lowest tree cost is chosen. The GA-based joint QoS multicast routing and channel assignment algorithm consists of sub processes like fitness function, selection scheme, crossover and mutation. The Simulated Annealing (SA) based joint QoS-MRCA algorithm consists of the sub processes like solution representation, neighbourhood structure, initial temperature, temperature decreasing, iterative length at each temperature and the termination rule. The TS operations consist of the sub processes like solution representation, initial solution, neighbourhood structure, fitness function, tabu move, tabu list, aspiration criterion and termination rule.

Utility-Based Multicast Routing and Channel Assignment

The Utility-based multicast routing and channel assignment (UBMR-CA) [Kumar et al., 2013] scheme provides an efficient and QoS aware routing and channel assignment service to the users also it incorporates features as low deployment and maintenance cost. In this scheme certain constraints are considered such as end to end delay, interference and available bandwidth which causes limitations to the overall QoS services availability to the end users. There are mainly two objectives of the scheme i.e. loop free routing and minimization of the total utility of a link in the network from a source to the destinations at any time. The term utility here is calculated using a utility weight metric (UVM) which is implemented for sending multicast messages from a single source to multiple destinations. The utility of the links are calculated using a utility weight metric (UVM) for sending and receiving messages through all links in the network. The channels for the links are assigned keeping in view the various constraints i.e. capacity, bandwidth and interference between different links. The utility of a link is the combination of its capacity, load and current interference with the neighbouring link. The utility of a link is subject to change with reference to changes in the capacity, link and interference with time. The UBMR-CA scheme constructs the utility based multicast tree, followed by the construction of the channel conflict graph and finally the utility based channel assignment. The UVM metric depends upon the number of interfaces, channel switching time, and number of available channels. The UVM is developed for multicasting and channel assignment according to the demand of the particular service required by the users. The metric has a great impact in aggregate throughput and delay which are the most critical for any application in WMN. The utility based channel assignment algorithm runs for initialization of an initial utility. The traffic patterns are divided into different groups, and depending upon it channels are allocated. In each time slot for every group the utility and channel assignment process are carried out. The channel assignment is not complete until utility of all members does not change in that group and in that time slot. The technique is also effective in achieving fairness between the various traffic flows, resulting in a good balance of the traffic load thereby improving the overall quality of the application and services provided by the WMNs.

Multicasting with Multiple Gateways and Partially Overlapped Channels

The Multicasting with multiple Gateways and Partially Overlapped Channels (MG-POC) framework [Shahmirzadi et al., 2016] is based on binary integer programming that provides framework for minimum interference in multicast communication. It provides a rational node selection to construct multicast tree that increases overall network performances. MG-POC efficiently constructs the paths between the source and the receivers by including minimal number of data forwarding nodes. It employs multiple gateways in order to reduce interference and usage of resources. Inclusion of the broadcast advantage of the wireless communication and usage of the partially overlapped channels in the channel assignment phase makes the scheme more advantageous. It solves the channel assignment and multicast tree construction problems simultaneously. MG-POC finds almost optimal solutions for large network problems in a reasonably short amount of time. It also supports multiple gateways and partially overlapped channels from the entire channel bandwidth. The framework also gives solutions that causes minimal network interference and enhances network throughput. MGPOC not only employs hop count as the routing metric in the multicast routing tree construction phase rather employs a rational node selection scheme. A Binary Integer Programming (BIP) is used to solve the problem, its efficiency and performance investigation. The rational node selection scheme constructs paths from a single source to the multiple receivers with a minimum

number of data relaying nodes. The MG-POC framework incorporates the Wireless Broadcast Advantage (WBA), which reduces interference and improves throughput. MG-POC also incorporates the multiple objective function with constraints as total number of forwarding nodes and the total interferences. A weakly decoupled approach is used to find a nearly optimal solution for fairly large network problems in a reasonably short amount of time. This technique uses physical interference model where communication between two nodes is successfully carried out only when the Signal to Interference and Noise Ratio (SINR) is above the permissible value or threshold. The multicast tree built in this scheme is a minimum cost tree which provides data transmission from Internet-connected gateways towards multicast receivers such that the multicast tree encompasses the set of all receivers related to the multicast communications. The multicast tree construction and channel assignment processes are solved sequentially where first the multicast tree is solved then the channel assignment process. In the multicast tree construction phase, a multicast tree is developed with minimum number of forwarding nodes. In the next phase the channel assignment is done where the total interference is taken as the objective function.

Multi Objective Optimization Approach for Joint Channel Assignment & Multicast

Routing

This scheme [Vaezpour et al, 2014] uses multi objective genetic algorithm to construct minimum cost multicast tree with minimal interference. It is achieved by optimizing the solution with constraints such as total channel conflict, tree cost, maximum end-to-end delay and average end-to-end delay. In other words, it produces a multicast tree with low interference, low cost and low delay. However the fourth objective, total channel conflict, is used in optimization of the channel assignment algorithm. For the overall improvement of the algorithm Evolutionary Multi Objective (EMO) algorithm namely, NSGA-II [Lobiyal et al, 2017] is used. NSGA-II is an optimization technique which can consider multiple optimization constraint at the same time and ranks the solution according to the non-dominance sorting and crowding distance. Since the multicasting data is transmitted the end-to-end delay, the network bandwidth usage, the delay jitter are specified in the multicast routing process. Reducing the overall cost reduces the resource usage as well as satisfies delay requirements thereby guarantying the data delivery with up to date data. Since data is transmitted along the multicast tree, the end to end delay, the network bandwidth usage, and the delay jitter are mainly specified by the multicast tree. The QoS is served as reducing the cost of the multicast tree helps in lowering resource usage. And the delay requirements of the multicast applications guarantees that the data delivered to the destination is up to date. Since the technique is NSGA-II inspired, the quality of the solutions against others is solved using Pareto ranking method. The Pareto dominance rule is used to sort the solutions and assigning them to the different fronts.

COMPARISON

In this section the QoS provisioning techniques have been compared. Table 1 shows the comparison of the schemes.

Table 1. Comparison of all the techniques, conditions applied and the QoS parameters served

Sl. no.	Algorithm	Conditions applied	QoS parameters
1.	GLBM[Zhao et al., 2010]	Multicast Routing	Packet loss, delay
2.	A Hybrid QoS multicast framework based protocol[Pourfarkhar et al., 2010]	Multicast Routing	Packet delivery ratio, packet delay, overhead.
3.	A QoS multicast routing algorithm[Ke et al., 2007]	Multicast Routing	Bandwidth requirements, end-to-end delay requirement and minimum cost.
4.	QoS Multicast Routing Framework [Shittu et al, 2008]	Multicast Routing	Delay, congestion overhead control.
5.	Escalating QoS with channel assignment and traffic scheduling [Salvakumar et al, 2018]	Channel Assignment	Throughput, energy, error rate.
6.	Capacity and interference aware link scheduling with channel assignment [Kumar et al, 2011]	Channel assignment	Aggregate throughput, packet loss rate, packet delivery, average end-to-end delay and fairness index.
7.	Q-CAR[Chakraborty et al., 2017]	Channel Assignment Multicast Routing	Interference disturbance, tree cost, SNR, delay, jitter.
8.	i-QCA[Chakraborty et al., 2015]	Channel Assignment Multicast Routing	Total co-channel conflict, tree cost, interference impact, radio interface cost.
9.	QoS-MRCA[Cheng et al., 2011]	Channel Assignment Multicast Routing	Channel conflict, tree cost.
10.	UBMR-CA[Kumar et al., 2013]	Channel Assignment Multicast Routing	End-to-end delay, interference, cost.
11.	MG-POC[Shahmirzadi et al., 2016]	Channel Assignment Multicast Routing	Interference, tree cost.
12.	Multi objective Optimization Approach for Joint Channel Assignment & Multicast Routing [Vaezpour et al, 2014]	Channel Assignment Multicast Routing	Total channel conflict, tree cost, end-to-end delay.

CONCLUSION

The main aim of this chapter is to study the QoS provisioning in wireless mesh networks when applied in different network phases, as channel assignment, multicast routing and in scenarios where channel assignment and multicast routing are jointly presented. The QoS is defined by the performance level of a service of a network with respect to some network parameters related to the service provided to the end users. QoS provisioning term is associated with the behaviour of wireless node or service of the network, throughput sensitiveness and delay sensitiveness in different applications of WMN. The inclination of research is towards QoS provisioning to the end users. As well as incorporating more independent parameters for overall improvement of the QoS of the network. The chapter presents different QoS scenarios in which QoS is expected by the end users of the network, requirements for providing QoS and challenges faced in the course of providing QoS. The QoS provisioning to the end users are further classified under three heads: QoS provision in multicast algorithm. QoS provision in channel assignment and QoS provision jointly in channel assignment and multicast routing. The existing techniques are discussed in brief under the three heads.

FUTURE RESEARCH DIRECTIONS

The algorithm, scenario in which it is applied and QoS parameter(s) served to the end users of the network is presented in tabular format. QoS provisioning and channel assignment considering more parameters such as traffic type is one of the future work directions. Moreover, such techniques for heterogeneous wireless networks also can be developed in future.

KEY TERMS AND DEFINITIONS

Channel Assignment: Channel assignment is the process of assigning separate orthogonal channel or partially over-lapped orthogonal channels to all the nodes in the communication range. The main motive behind assignment of channels is to reduce the interference impact and proper delivery of packets on time. For the WMN in channel assignment phase, the entire range of channels in IEEE 802.11 (a, aa, b, g, n) standard is utilized for assigning channels in the links. By the term link, it means the links between the mesh nodes. Channel allocation plays the most crucial role in achieving better performance of the network.

Multicast Routing: Multicasting is a mechanism where messages are transferred over links in the WMN once and are duplicated at the branch or break points in order to successfully deliver them to the different destinations. Multicasting is a form of communication that helps in delivering information from a single source to multiple destinations nodes simultaneously in an efficient manner. The multicasting routing is the process of selecting a route from a single source to multiple destinations. The multicast routing or simply multicasting cannot be attained by utilizing the concept of combined unicast from source to individual destination or simplified reduced broadcast from the source to all the receivers (Zeng et al., 2007). Multicast can transmit the same data flow to multiple destinations without producing the duplicate flow and without wasting bandwidth of the network (Choi et al., 2016). The main unit of multicast routing is the multicast routing tree. The various applications of the multicast routing includes audio/video conferencing, online gaming, remote learning, webcasting, distance learning, distribution of financial data, billing records, software, newspaper and lots more. To achieve efficient multicast communications, reasonable routing paths should be selected which connects all multicast receivers with the source node and also assignment of proper channels to the links of the network should be done (Wang et al., 2017).

Evaluating the Effectiveness of Multi-Web Services in Load Balancing Cluster-Based Web Server

INTRODUCTION

Web Service (WS) provides a flexibility platform for delivering computational task as service. Its architecture supports deployment of grid computing, Internet of Things (IoT) based applications and distributed computing in a flexible manner. The interoperable features of WS deployment support the homogeneous and heterogeneous communications among software modules.

It follows the principles of Service Oriented Architecture (SOA). The principles of SOA focus the methodology of service publishing, consuming and discovering over public registries. It supports service reuse and integration of additional service. The SOA is not limited to a technology. It can be implemented through the variety of programming languages, technologies and communication protocol. The power of Extensible Markup Language (XML) provides a framework in SOA for establishing communication among different business nodes. Recently, WS has become attractive paradigm for building the Software as a Service (SaaS). It is defined as SaaS for machine to machine interaction over different network topologies. The SOA offers the features of adaptability over different network connection and capabilities of terminals.

The principles of interoperability, reusability and modularity can be deployed through the methodology of WS. However, number of concerns and challenges are observed for the quality of the service (QoS). The QoS aspects can be observed from the perspective of service providers and consumers stakeholders. The service providers primarily concern about proper execution and implementation aspects of the service. Conversely, the service consumer primarily concerns about the quality assurance of the service. The service consumers also identifies whether the service is the right service for their business process or not. The service consumers usually identify the service over public service registries. The service can be executed and discovered at run time. Based on the functional parameter and business decision model, the consumer accesses the functionalities of the service. The service consumer is termed as WS client that can communicate the service provider and provide the additional service along with the existing service.

Many practitioners have been trying to deploy WS to deal with distributed business processes. Many prominent software industries are deploying their business services through the paradigm of WS architecture. Their primary goal is to deliver better and enhanced service to end users. With rapid growth of internet users, the consumer of WS is also increasing exponentially. As a service owner of WS, the

DOI: 10.4018/978-1-7998-3479-3.ch071

primary concern is to deliver the service to massive users even in high stress of usage. However, the load balancing cluster based web server can play a vital role for handling massive users of WS. The clustering methodology of web server using single or multiple machines can deliver reliable and efficient service to end users. With rapid growth of organizational infrastructure and independent service delivery modules, the deployment of multiple WS and assessing their effectiveness is becoming crucial among software practitioners and researchers. As such, the QoS against high load of users is becoming an important concern among research community. This work will introduce a novel QoS assessment framework for evaluating the effectiveness of multi WS deployment using load balancing cluster based web server.

BACKGROUND

WS provides the platform as framework for deploying software agents as service over network and enhances the functional execution of business process. It utilizes the different loosely or tightly coupled software services for business logics (BL). It provides conceptual as well as programmable interface for integration of modular oriented functional logic in a respective service (Matthew et al., 2005). The consumer of WS is not aware of internal data structure and the service platform that it is executing. The consumer simply utilizes the WS for the computational BL. The overall service that executes in server side and delivers service over network based protocol is termed as Service Oriented Computing (SOC). However, based on service delivery scenario and BL, the SOC based system may utilize the deployment of single or multiple WSs for service delivery. The SOC based system primarily utilizes SOAP, Web Service Description Language (WSDL), and Universal Description Discovery and Integration (UDDI). The software agents communicate through SOAP messaging that contains Extensible Markup Language (XML) nodes (SOAP, 2016). The publicity of the service is highlighted through WSDL file of the service. It establishes the connectivity and generates necessary server side files in client side (WSDL, 2016). The UDDI is the platform that showcases the required functional parameters of the service (Peiris et al., 2007). The block diagram of SOC based system and the different ways of WS communication are discussed elsewhere (Bora et al., 2016).

The SOC usually provides a framework for implementation and delivery of software agents, business process and logics over network based protocol. The SOC based model presents WS as loosely or tightly coupled software agents. It allows to present service as parent, broker or consumer of other service. Here, the consumer of service usually not aware of internal architecture of software agent being deployed. Their operational execution supports XML processing. The power of SOAP, UDDI and WSDL is being deployed for inter WS communication.

The WS can play the role of consumer, parent service (PWS) and child service (CWS). The WS can deliver services over network only through the web server. The web server processes the incoming Hyper Text Transfer Protocol (HTTP) request and delivers it to respective WS class files. Many researchers observed that (Saddik, 2006; Kalita et al., 2011; Bora et al., 2013; Bora et al., 2014), web servers have some limitations while handling massive request. Beyond a specific limit it fails for processing incoming request. However, the utilization of load balancing cluster based web server can enhance the processing capacity of web server up to a limit (Bryhni et al., 2000). The load balancing cluster based web server can be deployed through single or multiple machines. Different nodes can be created in the web server that can execute similar service for the end users. As such when a particular node fails in processing incoming HTTP request, the load balancer redirects it to other active nodes. The load balancer continuously validates whether the particular node is working with heavy load or idle in processing. As such

when a particular node fails or busy, the HTTP request is redirected to other nodes that are comparatively free in processing request. Thus, the overall capacity and performance is enhanced for service delivery. The deployment of this technique supports high availability, scalability and reliability against massive growth of end users. However, in the research community, identification stress limit beyond capacity, correlation and impact of different QoS metrics over WS execution and reliability beyond capacity of processing are gaining comparatively more importance.

OVERVIEW OF METRICS EVALUATION

Response Time

It is overall time required for processing the HTTP request and giving response to end users. The time unit is the parameter for estimation of service execution (Menasce et al., 2002).

Throughput

It highlights the data bytes process in server side. The measurement unit is bytes per seconds (Menasce et al., 2002).

CPU Utilization

It shows the utilization of processing resource during high stress of server execution. The measurement unit is usually the percentage of server execution (Singh et al., 2015).

Reliability

Reliability highlights the probability that the WS will deliver valid response to the consumer. The measurement is usually carried out through observation fault count within specific time interval. Many reliability models are there that can be used to analyse the fault tolerance of a service (Goel, 1985).

Related Work

Many researchers had carried out and presented their investigations over deployment of WS for computational implementation. However, there is a lack of study that specifically highlights the concern quality metrics of WS deployment during high stress of users.

Pacifici et al. had presented architecture for server overload and performance management of service during high stress of users (Pacifici et al., 2005).

Anzbock et al. had demonstrated a model for WS as middleware service deployment (Anzbock et al., 2005). They had evaluated a data sample to validate the WS execution.

Castro et al. had discussed a model for development of medical business process through different web technologies (Castro et al., 2006). However, the study lacks of experimental evaluation of the work.

Zhang et al. had presented a queuing model for performance aspects of load balancing web server (Zhang et al., 2008). Their experimental study highlighted the system metrics including response time and rejection rate of routing model for web server.

Medhi et al. had discussed a WS oriented Automatic Teller Machine (ATM) and shown some performance metrics using .NET framework (Medhi et al., 2014).

Kilintzis et al. had discussed the key aspects of deploying WS for data store operations. Their experimental results had validated the applicability of the work (Kilintzis et al., 2014).

Ismail et al. had discussed an approach for internal and external assessment of the service deployment (Ismail et al., 2015). An experimental study was carried out to establish the applicability of the work.

Medhi et al. had highlighted the reliability evaluation framework considering fault tolerance record of the WS using SOAP based Microsoft Windows Communication Foundation (WCF) service (Medhi et al., 2017).

Jiang et al. had demonstrated a study of reliability management for deployment of single service oriented WS (Jiang et al., 2017).

Abdelfattah et al. had discussed about reliable service architecture for ensuring service communication under different system constraint (Abdelfattah et al., 2017).

Zhou et al. had introduced a novel methodology for comparing security attributes and values for end users (Zhou et al., 2017).

Bora et al. had discussed failure and reliability aspects of SOC based system based on different deployment technique (Bora et al., 2018). The experimental study demonstrated the comparative key aspects of WS deployment using Tomcat and Microsoft IIS web server.

Yamada et al. had presented an analysis model to validate the smart grid based system through the aggregation of WS (Yamada et al., 2018).

Nato et al. had demonstrated a testing methodology for characterization of semantic WS (Nato et al., 2018).

The proposed work is novel from precious work as it will discuss a QoS framework for evaluating the effectiveness of performance and reliability factors of SOC based system with multiple WS against massive load of request. The study will also highlight the correlation of system metrics such as response time, throughput, CPU utilization, load testing, fault analysis and reliability evaluation against different loads of user. The system metrics will be evaluated through statistical analysis to establish the effectiveness of WS in cluster based web server.

FOCUS OF THE ARTICLE

The focus of the work will be given on effectiveness of WS using load balancing cluster based web server. The key aspects of clustering different nodes of web server and deploying multi WS over there will be another focus for the work. The emphasize is given over the performance and reliability metrics of WS execution in cluster based web server as the end users visualizes them before utilization of service.

An architecture of multi WS communication is taken for the study that contains parent, broker and child WS and executes together to fetch record from database. The architecture of the service deployment is shown in Figure 1. In this study, the web server load is distributed in round robin scheduling fashion and the web server clustering is carried out through configuration of Apache Tomcat Application Server, mod_jk tomcat connector and Apache Http Web Server. The WS is developed and implemented using JAVA with Spring framework Model View Controller (MVC) version 2.5 and MySQL database server. A database mapping of 15000 records for disease medicine clinical remarks is taken for the study. The load in the system is given through the load testing tool Mercury LoadRunner version 8.1 that generates virtual users (VU) for accessing the system (Mercury LoadRunner, 2018). A flow chart for evaluating the effectiveness of the service is prepared and shown in Figure 2.

Figure 1. The architecture of service deployment

A test case is designed that contains instructions for the VU about how to access the system. The test case is discussed elsewhere at (Bora et al., 2014). All VU follows the test case. The Tomcat Application Server is clustered into different nodes running the same multi WS architecture. The load distribution of incoming request is handled by configuring Apache Http Web Server along with mod_jk tomcat connector. An extensive statistical analysis is performed over a data sample of recorded metrics considering response time, throughput and CPU utilization along with the failure density of the service. The hardware and software specification that will be used are: 64-bit Windows Server 2008 R2 Standard operating system (OS), Intel® Xeon® CPU E5620 @ 2.40 GHz processor, 8GB RAM, Apache Tomcat version 7 application server, Apache HTTP server version 2.2.4 web server, MySQL version 5.0 database server, 600 GB hard disk, Mod JK Tomcat connector, Java Development Kit of version 7, Java Runtime Environment of version 7, Spring MVC 2.5 framework, Metro WS stack, NetBeans Integrated Development Environment of version 7.0, Google Chrome web browser. The load will be generated using a machine with hardware and software specification as Windows XP OS, Intel® Pentium® Dual CPUE2200 @ 2.20 GHz processor, 1GB RAM, 150 GB hard disk and Mercury LoadRunner load testing tool of version 8.1.

Figure 2. Flowchart for evaluating the effectiveness of the service

SOLUTIONS AND RECOMMENDATIONS

Rigorous testing and deployment of statistical analysis are considered to be good candidature for evaluating the applicability and effectiveness of a system (Kalita et al., 2011). To study the effectiveness of the service, the SOC based system is evaluated against the load of 50, 100, 800, 1500, 1700, 1800, and 2000 VU level. The mercury load runner is deployed for generating different VU level. The necessary test case for accessing load balancing cluster based web server is created. All stress level of VU follows

Table 1. Recorded results against different loads of VU for two working node cluster based server (R_T : Response Time, s; T_{HPT} : Throughput, bytes/s; CPU_{UT} : CPU utilization, % ; TP: Transaction passed; TF: Transaction failed)

VU level	Average of Recorded parameters			TP	TF	Failure rate (%) = TF/(TF+TP)
	R_T	T_{HPT}	CPU_{UT}			
50	11.69	2368.013	3.88	287	0	0
100	11.86	4013.95	6.16	695	0	0
800	11.93	6394.106	19.246	19,566	0	0
1500	11.98	7324.544	21.094	62,968	0	0
1700	11.347	8592.85	22.161	80,040	0	0
1800	25.28	105729.1	39.13	82387	43836.1	0.35
2000	26.31	18251.2	43.6	91345	69251	0.43

the same script. Each execution of test case causes the event of establishing the client server communication through WSs. Each request causes the inter WS communication for processing BL. The test bed is set up in such a way that all VU will enter gradually the ramp up period of server and will execute together. During this ramp up period the measurement parameter such as response time, throughput and CPU utilization along with HTTP transaction passed and failed is being recorded through mercury load runner. However, after ramp up time, all VU exits the system simultaneously. The test bed is executed till the SOC based system throws HTTP transaction errors. Here, the failure records shows against the stress level of 1800 and 2000 VU. The failure record is observed to be increasing gradually beyond this limit. The effectiveness of the service against different stress level of VU is shown in Table 1. It is observed the recorded parameters are increasing with increase in stress level of VU.

Figure 3. Response time of the service against VU stress level of 100.

Figure 3 shows the recorded sample response time of the service against 100 VU. It is observed to be increased with the increase in stress level.

Distribution of Response Time

To study the distribution of response time of the service, a data sample of 30 repetitive tests against 50 VU stress level is taken of the study. The histogram is plotted against the data sample of recorded response time. The histogram is shown in Figure 4. It shows that the distribution follows normality with single peak value. However, based on different class sizes, different assumption may be interpreted. As such, the normal probability plot (NPP) is interpreted against the recorded response time. The NPP is a graphical interpretation technique that shows the normality of the recorded data points against theoretical quantile parameter (NIST, 2017). The NPP of the recorded response time is shown in Figure 5. The NPP of response time shows that the response time of the service follows a straight line. As such the recorded data sample can be interpreted to be linear and normally distributed. That means, the recorded data points are valid and follows the mean of the response time.

Figure 4. Histogram of response time

Correlation of Recorded Metrics

To study correlation of the recorded parameters, we deploy the regression analysis. A hypothesis (H_0) is considered that the response time, throughput and CPU utilization are correlated and the throughput

Figure 5. NPP of response time

and CPU utilization together have impact over the response time. At 95% confidence level, the study of multiple linear regression analysis is carried out and shown in Table 2.

Table 2. Multiple linear regression analysis of recorded data sample

F ratio	F table critical value F(2, 27)	Is F ratio > F table critical value?	Adjusted R ²
5.4	3.354	Yes, Accept H ₀	23.3%

This validates the H₀ and concludes that recorded parameters are correlated and the response time is influenced by the recorded throughput and CPU utilization of SOC based system.

Evaluation of Reliability and Fault Count

The effectiveness of the reliability can be evaluated through the study of recorded HTTP fault count. The recorded experimental parameter as shown in Table 1 shows that the first HTTP failure occurs at the stress level of 1800 VU. As such, to study the mean fault count and reliability aspects of the service, we repeatedly tested the service against 1800 VU for 30 times. The histogram of the recorded fault count data sample is shown in Figure 6. It shows a mean HTTP fault count of 43836.1 and lies in the range of 41335.5 to 45365. The reliability of the service can be evaluated using equation (1) as defined by (Shooman, 2002, Rahmani et al., 2014, Medhi et al., 2017).

Figure 6. Histogram of recorded fault count

$$R = e^{-ft} \quad (1)$$

Here, the R metrics shows the reliability of the service. It is evaluated using failure rate 'f' as observed during 't' exposure period of the service. The R predicts the probability of valid execution of WS along with load balancing cluster based web server. That is, with valid value of R predicts that the WS will provide the searchable information during exposure period. Equation (1) evaluates a value within a range of 0 to 1. A value nearer to 1 predicts strong reliability. A service with poor reliability will have a value nearer to 0. In this case, 'f' value for the recorded 1800 VU data sample is observed to be 0.35%. As such, the R is evaluated and observed to be 0.7. As such strong reliability may be assumed with a probability that 70% of its exposure period will be served during invocations by 1800 users.

A comparative evaluation with other author's work is carried out to study the reliability and stability assessment of the proposed deployment. It is shown in Table 3.

It is observed from Table 3, that up to a stress level of 1700 VU, the failure rate 0. That means strong reliability can be observed during the stress. However, in case of (Saddik, 2006), the first failure rate is 60.28% for a stress of 100 VU. Similarly, in case of (Kalita et al., 2011), 50% of failure rate is observed

Table 3. A comparative assessment of the proposed deployment with other authors work

No. of VU	FR % of proposed study	FR % of earlier study done by other researchers		
		Saddik, 2006	Kalita et al., 2011	Medhi et al., 2014
50	0	Not Tested	0	0
100	0	60.28%	50%	0
500	Not Tested	87.9%	Not Tested	0
800	0	Not Tested	Not Tested	Not Tested
1000	Not Tested	92.06%	Not Tested	37%
1500	0	Not Tested	Not Tested	75%
1700	0	Not Tested	Not Tested	Not Tested
1800	35%	Not Tested	Not Tested	Not Tested

against 100 VU. Similarly, in case of (Medhi et al., 2014), 37% of failure rate is observed against 1000 VU. In the proposed methodology, the service is throwing first failure response against the stress of 1800 VU. As such it can be assumed that the proposed methodology of deployment gives better reliability and stability in comparison to other's deployment technique. It can also be concluded that efficiency, reliability and stability of multi WS paradigm with load balancing cluster based web server is better than other deployment technique. The expectation of service efficiency is also high during peak usage of the service. However, the system may generate failure record after maximal capacity of processing limit. As such SOAP request response processing error can generate and hamper the service delivery standards. The overall assessment concludes that segregation of role such as parent, broker and child service among different WS is better than merging the roles into a single WS.

FUTURE RESEARCH DIRECTIONS

As part of future work the proposed framework can be deployed for grid based system where WS will deliver services through independent machines. A proper fault tolerance methodology can be deployed for handling failure request and routing to the specific node for service delivery.

CONCLUSION

The work emphasizes the quality assessment framework for deployment of WS in load balancing cluster based web server. Deployment of different clustering nodes describes different aspects of effectiveness of the service against massive growth of users. The stability and reliability of the WS is observed up to 1700 load of users. The correlation of system metrics highlights that with increase in usage level, the system metric increases. A strong reliability can be assumed up to a specific load level of 1700 VU. Beyond that, moderate reliability can be assumed. Each stress generation through VU over the server causes SOAP communications among WSs. As such, with increase in stress level the response time, throughput and CPU utilization increases proportionally. The normality of data distribution is observed for the recorded data sample. This reveals that the population of the data sample follows the mean of recorded parameters. The effectiveness of the proposed work against high usage of the service is observed to be

better than other's deployment technique. This work precisely describes the quality evaluation framework along with the experimental results. As such, the software practitioners and researchers can get an in depth idea about the quality factors of WS against high load of users and the key metrics degrading the quality and reliability of the server. From the study and experimental results of the work the authors can conclude that the quality evaluation framework considering WS based system in load balancing cluster based web server will be viable, acceptable and applicable. The experimental results and evaluation of the work can help researchers and software developers to focus an idea about the quality of WS in load balancing cluster based web server.

ACKNOWLEDGMENT

The authors express their sincere thanks to All India Council of Technical Education (AICTE), Govt of India for financial support towards the work (Grant No. 8023/BOR/RID/RPS (NER)-84/2010-2011 31st March 2011).

KEY TERMS AND DEFINITIONS

Load Balancing Cluster Based Web Server: It is a methodology where web servers can be clustered and loads among them can be balanced through load balancer server.

Load Testing: It is a testing candidature usually carried out to study the behaviour of a system against excessive load.

Service-Oriented Computing: It is framework for deployment of WS where we can configure and develop necessary WSDL, SOAP message structure, and BL method for both client and server side.

Test Case: It is a collection of instruction for the testing module. It highlights the way a tester will follow for testing the service.

WS Scalability: It is a term used to describe how scalable a system is. A WS is scalable if it can handle massive request efficiently.

WS Stability: It is a term used to describe how stable a system is. A WS is stable if it can execute without any error while processing incoming HTTP request.

Challenges and Opportunities of VLC Application in Intelligent Transportation Systems

INTRODUCTION

Visible Light Communication (VLC) is a developing wireless communication technology, which uses visible light (380 - 780 nm) for data transmission. It offers significantly greater bandwidth compared to the radio frequency (RF) communications. VLC exploits the low-cost and highly efficient Light-emitting Diodes (LEDs) used for both illumination purposes and wireless communications. LEDs are characterized by numerous advantages, including long lifespan, compact form factor, reduced usage of harmful materials in design and low heat generation even after long period of usage. Another important benefit of LEDs is the capability of switching to different light intensity levels (undetectable to human eyes). Furthermore, VLC is safe for human health and it does not affect the functionality of the sensitive electronic systems. It is also characterized by a high directivity and a predictable channel, which reduces the sources of interference and a high-security level is guaranteed due to the inherently reserved channels. These benefits make VLC a very promising technology for numerous applications. However, the high directivity requires the existence of the Line-of-Sight (LOS), which limits the use of VLC. Relative mobility in establishing communication links between vehicles or between vehicles and infrastructure can disrupt LOS. In addition, natural and artificial light also degrades performances of the VLC systems, especially the sunlight which adds noise and interference in the channel.

VLC enables wireless communications with high data rates wherever there is artificial lighting, indoor and outdoor. Thus, VLC has great potentials in vehicular communication applications. It can easily be incorporated into Intelligent Transportation Systems (ITS). The aim of ITS is to increase safety, the efficiency of the transportation system and to reduce the gasses emissions. Numerous studies show that VLC can satisfy the requirements imposed on vehicular networks. Various modes of vehicular communication can be established: Vehicle-to-Infrastructure (V2I), Vehicle-to-Vehicle (V2V) and Infrastructure-to-Vehicle (I2V). Considering the communications between infrastructure and vehicles, and vice versa, most of the existing systems are oriented towards the communication between LED-based traffic lights or street lighting system and vehicles. The high power of traffic lights allows relatively long communication distances. On the other hand, the short distance between the street light and vehicle, along with the high power implied, assures high data rates and increases the communication stability. Based on the LED lighting systems integrated into vehicles in headlamps, brake lights or signal lights, the VLC communication between vehicles is enabled. Besides communication, VLC enables positioning superior to the Global Positioning System (GPS) with lower costs than existing systems. In this chapter, the

DOI: 10.4018/978-1-7998-3479-3.ch072

comprehensive analysis of VLC technology and applications in ITS are provided. Main characteristics of VLC in ITS in terms of architecture, modulation and standardization are analyzed. Benefits and possible challenges of VLC application in ITS scenarios are also addressed.

BACKGROUND

Transportation systems play an important role in modern life. The advancements in communication technologies and their application in transportation systems have led to the introduction of the concept of Intelligent Transportation Systems (ITS). A subset of the ITS, in which participants communicate and share information is called Cooperative Intelligent Transportation Systems (C-ITS). C-ITS aims at improving safety, sustainability and efficiency. C-ITS consists of the following four entities: personal, vehicle, central and roadside (ETSI EN 302 655 v.1.1.1, 2010). Personal entity enables access to ITS applications using personal devices, such as Smartphone with location-based applications. Vehicle entity consists of the vehicle on-board equipment (on-board unit, OBU) which hosts ITS applications. These vehicular ITS applications gather information about the vehicle and its environment and provide partial or full control over the vehicle in critical situations. Central entity comprises the equipment used to maintain, monitor and provide functionality to ITS applications. Finally, roadside entity, also referred to as Roadside unit (RSU), provide the equipment placed along the roadside which hosts ITS applications. The roadside ITS applications communicate with the vehicular ITS sub-systems together information about road environment, traffic conditions and control roadside equipment. A Multi-tier ITS architecture is proposed by Lin, Wang and Ma (2017). This structure provides guarantees in terms of interconnection, operation and service. It consists of the physical layer, the communication layer, the operation layer and service layer. Physical layer comprises vehicles, infrastructure and end users. Communication layer enables data transmission between ITS elements. Communication options provided by the communication layer include Field-Vehicle Communications (communications between vehicles and infrastructure), Fixed Point-Fixed Point Communications (communications between stationary entities), Vehicle-Vehicle Communications (short-range communications between vehicles) and Wide Area Wireless (Mobile) Communications (communication between vehicles and end user mobile devices). In general, ITS applications rely on Vehicle-to-Infrastructure (V2I), Vehicle-to-Vehicle (V2V) and Infrastructure-to-Vehicle (I2V) communications. There are three main classes of ITS applications: Road/Traffic Safety, Traffic Efficiency and Value-added applications (ETSI EN 302 655 v.1.1.1, 2010). Traffic safety applications aim at minimizing the risk of undesirable situations and reducing the damage of unavoidable accidents. The improvement of traffic conditions (in terms of travel time and traffic congestion) is a primary goal of traffic efficiency applications. Traffic information is usually gathered by roadside infrastructure and transmitted to the user. Value-added applications include providing Internet access, travel information and planning. The goals of these applications are comfort and convenience for the end users.

ITS involves cooperative wireless communication technologies to provide data exchange between vehicles or between vehicles and infrastructure. Current ITS research activities, products and standardization are mainly based on radio frequency (RF) communication technologies. Due to numerous advantages, VLC is considered as a promising candidate technology for vehicular communications (Khan, 2017). The primary advantage of VLC is the possibility of deployment in vehicular environments using existing infrastructure, which makes VLC a low complexity and low-cost technology. Highly directional Line-of-Sight (LOS) enables positioning with high precision. The positioning error is up to tens of centimetres, which is more accurate than the RF-based positioning technology (Armstrong, Sekercioglu

& Neild, 2013). In addition, VLC systems are characterized by high scalability (You, Chang, Lin & Tsai, 2013). In the periods of heavy traffic densities, RF communication systems experience undesirable packet collisions, longer delays and poor packet reception rate. On the other hand, VLC systems allow only communication between vehicles that reach LOS. Thus, signal congestion is significantly reduced. Furthermore, VLC enables high data rates, due to vastly available bandwidth. The potential of VLC as a complement or an alternative to RF technologies in vehicular communications is analyzed by Cailean, Cagneau, Chassagne, Popa and Dimian (2014). A comprehensive comparison of RF and VLC in vehicular communications in terms of conditions in communication channel: physical waves, radiation pattern and path loss modeling, noise and interference and performance modeling is provided by Cheng, Viriyasitavat, Boban and Tsai (2017). A VLC-based I2V communication system is analyzed by Kumar, Lourenco, Teraa, Alves and Aguiar, (2012), where a LED-based traffic light is used as an RSU for traffic information broadcast. VLC based V2V communication system with an LED-based transmitter and a camera receiver is proposed by Takai, Harada, Andoh, Yasutomi, Kagawa and Kawahito (2014). Another system based on LED transmitter and camera receiver convenient for V2V and V2I applications is proposed by Takai, Ito, Yasutomi, Kagawa, Andoh and Kawahito (2013). This system achieves the data rate of 10 Mbps per pixel or more for concurrent sending of video data and vehicle internal data, such as vehicle speed, braking status, etc. In addition, this system enables real-time detection (Takai, Ito, Yasutomi, Kagawa, Andoh & Kawahito, 2013). Luo, Ghassemlooy, Le Minh, Bentley, Burton and Tang (2014) analyzed VLC V2V communication models based on LOS and Non-Line-of-Sight link configurations. The model determines the relation between the communication range and the system Bit Error Rate (BER). It appears that placing a photodetector at a height of 0.2 - 0.4 m above the road surface in the vehicle, the communication range can be lengthened up to 20 m at a data rate of 20 Mbps. Cooperation between VLC based I2V and V2V communications is observed by Cailean, Cagneau, Chassagne, Topsu, Alayali and Dimian (2013). Node to node communication is used to limit the interferences caused by multiple transmitters in the communication range. That system achieves BER of 10^{-7} for the both I2V and V2V ITS segments. In addition, it is possible to maintain low BER while increasing the distance between the transmitter and the receiver.

VLC outdoor applications need to solve several challenges (Vappangi & Mani, 2019). In general, the dynamic nature of the vehicular environment and the weather conditions cause that the VLC channel is very unpredictable. The major problem for outdoor VLC application is triggered by the numerous sources of parasitic light. Besides the artificial light sources, the sunlight represents the most powerful source of the noise. VLC channel conditions can be further deteriorated by snow, dust, fog or raindrops. Any obstacle that can obstruct the communication path affects the power of the received signal. Another important challenge for VLC implementation in vehicular applications is to enable data transmission at large distances. More efficient photosensitive elements need to be integrated to enable low-power signals detection, and hence, to enable longer communication ranges. Therefore, increasing the robustness to noise is an important issue to be solved for vehicular VLC applications.

KEY CHARACTERISTICS OF VLC IN ITS SCENARIOS

In this section, the architecture, modulation techniques and standardization issues of VLC in the segments of ITS are analyzed.

A VLC system comprises the VLC transmitter and the VLC receiver. The VLC transmitter is an optoelectronic transducer that modulates the light from a LED luminaire. The LED luminaire consists

of a LED lamp, ballast, housing and other components. The LED lamp consists of one or more LEDs and a driver circuit which controls the brightness. When a LED luminary is used for communications, the driver circuit is modified to enable modulation. Since the VLC systems are used for both illumination and communication, the major requirement in the VLC systems is that illumination should not be affected due to communication. The VLC receivers can be classified into two types: photodetector (also referred to as photodiode or non-imaging receiver) and imaging sensor (also referred to as camera sensor). The photodetector is a semiconductor device that samples the received light and converts it into electric current. An imaging sensor requires a lot of photodetectors for high-resolution photography. Very-low-data rates can be achieved using imaging sensors. However, the data rate can be improved using the “rolling shutter” effect (Pathak, Feng, Hu & Mohapatra, 2015).

There are three possible VLC link realizations: directed LOS, non-directed LOS and diffused non-LOS. The directed LOS requires the precise alignment between the VLC transmitter and the VLC receiver. Therefore, it enables the highest throughput and the longest distance. In the case of the non-directed LOS, the requirements in terms of the alignment are less strict. However, only shorter distances can be achieved and medium to high throughput is provided. The diffuse non-LOS does not impose any alignment requirements. As a result, the lowest throughput is provided and it is convenient only for indoor use.

The light signal is characterized by the non-encoding properties of the data in phase and amplitude. Therefore, the data in VLC systems need to be encoded using variations in the intensity of the light emitting wave. It is important to emphasize that any modulation technique in VLC should not only achieve higher data rate but also satisfy the requirements in terms of dimming and flickering of perceived light to humans (Pathak, Feng, Hu & Mohapatra, 2015). Different levels of illuminance are needed for different environments. Thus, an illuminance in the range of 30 - 100 *Lux* is convenient for public places. Indoor applications require higher illuminance. Nowadays, LEDs support dimming at an arbitrary level depending on the requirements and hence, it is possible to achieve significant energy savings. The fluctuations in the brightness of the light, i.e. flickering effect can be very harmful to human. Therefore, the light intensity should change at a rate faster than the human eye can perceive. According to IEEE 802.15.7 (2011), flickering should be faster than 200 Hz.

The following modulation techniques are commonly used: On-Off Keying (OOK), Pulse modulation techniques and Color Shift Keying (CSK).

OOK modulation technique represents the transmission of bits “1” and “0” by turning the LED on and off, respectively. During the OFF state, the light intensity is reduced. Major advantages of OOK are simplicity and ease of implementation. The white LEDs are most commonly used for OOK modulation in VLC. It is possible to achieve 10 Mbps using Non-Return-To-Zero (NRZ) OOK with the white LED (Park, Jung, Shin, Hyun, Lee & Oh, 2007). A blue filter can be used to enhance the data rate up to 40 Mbps. In addition, the blue-filtering with analogue equalization at the receiver enable data rate of 125 Mbps (Vucic, Kottke, Nerreter, Habel, Buttner, Langer & Walewski, 2009). The performance can be further improved by using an avalanche photodiode at the receiver. The combination of the avalanche photodiode and NRZ-OOK enables data rates up to 230 Mbps (Vucic, Kottke, Nerreter, Habel, Buttner, Langer & Walewski, 2010). The data rates up to 477 Mbps can be achieved using RGB white LED and NRZ-OOK modulation, where only the red LED is modulated for data transmission while the other two are provided with the constant current for illumination.

Various modulation techniques based on pulse width and position are used to enable higher data rates, especially when supporting different dimming levels. In Pulse Width Modulation (PWM) the widths of the pulses are different for different dimming levels. The advantage of PWM is that enables dimming without changing the intensity level of pulses. Hence, the colour shift in the LED is avoided. The major

limitation of PWM is the low data rate of up to 4.8 Kbps (Sugiyama, Haruyama & Nakagawa, 2007). In Pulse Position Modulation (PPM), the symbol duration is divided into slots of equal duration and a pulse is transmitted in one of the slots. The position of the pulse determines the transmitted symbol. Due to limitations of low spectral efficiency and low data rate, variations of PPM technique are proposed. Overlapping PPM (OPPM) allows more than one pulse to be transmitted during the symbol duration, while the different pulse symbols can overlap (Shiu & Kahn, 1999). Compared to PPM and OOK, OPPM achieves higher spectral efficiency and a wide range of dimming levels, along with the high data rate (Bai, Xu & Fan, 2010). Multipulse PPM (MPPM) also allows multiple pulses to be transmitted during the symbol duration, but the pulses within a symbol duration do not have to be continuous. Compared to OPPM, MPPM improves spectral efficiency (Sugiyama & Nosu, 1989). Spectral efficiency can be further improved using a combination of OPPM and MPPM, referred to as Overlapping MPPM (OMPPM). OMPPM enables that more than one pulse positions are allowed for each optical pulse. Moreover, Expurgated PPM (EPPM) is a modulation technique where symbols in the MPPM are expurgated to maximize the inter-symbol distance. EPPM provides dimming support as it can achieve an arbitrary level of illumination by changing the number of pulses per symbol and the length of the symbol. In addition, EPPM mitigates the flickering. Multi-level EPPM (MEPPM) supports multiple amplitude levels in order to improve the constellation size and spectral efficiency. It also supports dimming and flickering-free communication. A hybrid modulation technique comprising PPM and PWM is referred to as Variable PPM (VPPM). VPPM allows that bits are encoded by the different position of the pulse, while the width of the pulse can also be modified.

The white light can be generated using three separate LEDs, Red, Green and Blue (RGB), often referred to as TriLED (TLED). CSK modulation technique modulates the signal using the intensity of the three colours in the TLED source. Compared to other modulation techniques, CSK improves the data rate and it is based on the colour space chromaticity diagram (Pathak, Feng, Hu & Mohapatra, 2015).

Standardization initiatives are of great importance for further VLC integration in ITS scenarios. Two organizations are in charge of VLC standardization: the Visible Light Communication Consortium (VLCC) in Japan and the IEEE. The Japan Electronics and Information Technology Industries Association (JEITA) CP-1221, JEITA CP-1222 and JEITA CP-1223 are published by the VLCC. These standards mainly consider position detection applications. However, they are not commercially exploited. The first official VLC standard is provided by the IEEE 802.15.7 (2011). The aim of the standard IEEE 802.15.7 is to provide the access to several hundreds of THz bands, to prevent electromagnetic interference and to provide physical layer specifications, such as optical mapping, flickering and dimming mitigation etc. This standard should also support applications related to VLC Personal Area Networks (VPAN). It comprises both the physical layer (PHY) and the medium access control (MAC) layer for short-range optical wireless communications using visible light in optically transparent media. There are three types of the physical layer: PHY I, PHY II and PHY III. These layers can employ different modulation techniques and different data rates can be achieved. Thus, PHY I, PHY II and PHY III enable data rates in the range 11.67 - 266.6 kbps, 1.25 - 96 Mbps and 12 - 96 Mbps, respectively. For most ITS applications, PHY I type is the most convenient, since it is designed mainly for outdoor applications. PHY I typically uses OOK and VPPM modulation techniques. Although it provides the lowest data rates, it is possible to eliminate the additional path loss due to longer distance and potential interference from daylight and fluorescent lighting (Falcitelli & Pagano, 2016).

POSSIBILITIES OF VLC APPLICATION IN ITS

Integration of VLC systems in ITS architecture can play a significant role in the improvement of various aspects of transport and traffic engineering (Kostic-Ljubisavljevic, Radonjic Djogatovic & Mikavica, 2017). The transportation lighting infrastructure, such as street lighting, traffic lights, vehicular lamps, etc., are switching to LED lighting. This is a huge potential for low-cost VLC integration into the ITS environment. RSUs such as LED-based traffic lights can be used for information broadcast, as shown in Figure 1.

Figure 1.

This information is then detected by receivers installed in vehicles, thus enabling I2V communications. Therefore, traffic safety information can be broadcasted without additional energy consumption. Furthermore, this information can enhance traffic flows and reduce accidental situations, as well. Due to straight light propagation, it is possible to achieve high-directional communications. Thus, different traffic information can be transmitted for different lanes of a road. Vehicles can also communicate with adjacent vehicles using head, tail or brake lights, thus enabling V2V communications. Potential applications of VLC-based V2I and V2V communication systems include active road safety, traffic efficiency, local services and Internet-based services. More VLC applications in ITS are explained below.

Traffic safety can be significantly improved by VLC based road surface detection. Three mechanisms occur when the light beams the surface: reflection, transmission and absorption. The diffused reflection is the reflection of light from a rough surface when an incident ray is being reflected in many angles. Some rays are reflected back around the angle of the incident ray. When the road surface is wet, two scenarios are possible. At first, water fills holes in the surface and enables a specular diffusion when an incident ray is being reflected at one angle. Thus, the diffused reflection is minimized. The other situation occurs when the water level is deep enough to provide a total internal reflection within the water puddle. Therefore, the diffused reflection depends on the water depth on the surface. Every change in the water level on the surface can be measured using a LED fog lamp to beam the surface and then receive the reflection from a photodetector placed within the headlight compartment (Cahyadil, Kim, Chung & Ghassemlooy, 2015).

Combining VLC-based V2V communications and visible-light positioning can improve vehicle safety systems. VLC lights can concurrently provide illumination and signaling, reliable communications and accurate positioning (Yu, Shih, Tsai, Wisitpongphan & Roberts, 2013). Such a system is characterized by low complexity and it is scalable in high vehicle density. Each vehicle in this system can create a map

that contains the relative positions, speed, brake status, and heading of the surrounding vehicles that reach LOS. Using the map with the estimated positions of surrounding vehicles, the driver can adjust the vehicle's speed or heading to avoid accident situations. Information about stopped and overtaking vehicles are also provided. Furthermore, the trajectories of the surrounding vehicles in the next few seconds can be estimated. Another system for traffic safety improvement provides a map with positions and speed of all surrounding vehicles, including those in nearby lanes (Yu, Shih, Tsai, Wisitpongphan & Roberts, 2013). Thus, when the driver indicates the willingness to change a lane, the system analyzes the map and signalizes when the lane change can be executed safely. This application requires very accurate positioning to identify the lane of each surrounding vehicle, which VLC can assure. Collision risk is also high at road curve lanes. In situations where the curve width only allows one vehicle to pass through each time, a VLC terminal equipped with LED indicator can be located outside the road curve lane to communicate with vehicles on both sides (Qiao, Xia, Hong & Shen, 2017). Whenever one vehicle is going into the curve lane, an alarm signal should be triggered and released to indicate another vehicle to reduce the speed or to stop. In such a system, as shown in Figure 2, a stop line and a warning line should be set. Thus, the vehicle first reaches the warning line and send the VLC signal to the VLC infrastructure terminal. Then, the VLC terminal broadcasts warning signals in the area that covers the whole curve lane. When the vehicle approaches the stop line, if there comes another vehicle at the same time it receives the warning signal to decrease the speed or to stop.

Figure 2.

Positioning using VLC becomes an active research topic, especially for traffic safety improvement. Global Positioning System (GPS) lacks in provisioning accurate location information in high-density traffic conditions or in the city zones with high surrounding buildings. Outdoor VLC positioning systems

provide vehicles and pedestrians more accurate location service. In an outdoor environment, the main light source can be traffic lights, vehicle headlights/taillights, or street light posts. Outdoor applications are exposed to some challenges. At first, the lights can be poorly distributed or moving with the presence of ambient noise. Furthermore, real-time positioning of fast-moving vehicles is highly challenging. However, VLC based outdoor positioning has many advantages and main applications are described as follows.

Besides their main function as a signaling device, LED-based traffic lights can be used for continuous provisioning of positioning service for vehicles in its vicinity. The outdoor positioning can be performed using one or two traffic lights and two photodiodes (Bai, Chen, Xu & Fan, 2011). The signal, containing the light position information, is emitted from the traffic light. Two photodiodes are mounted on the front lights of the vehicle. Their centre is the required position of the vehicle. In the single-traffic light scenario, two photodiodes perform measurements of Time Difference of Arrival (TDOA) of the traffic signal when the vehicle is moving to another location. These measurements create two sets of the hyperbola. The observed vehicle is located within the area formed by the crossed points of these hyperbolas. The scenario with two traffic lights involves a vehicle traffic light and a pedestrian traffic light. Each light is modulated in different frequencies. Two photodiodes measure the TDOA simultaneously. Based on these measurements, it is possible to obtain the relative position of the traffic lights to the vehicle and the absolute position of the vehicle.

VLC system based on an image sensor can be used for V2V positioning, as shown in Figure 3 (Tram & Yoo, 2018). Cameras are embedded in the estimating vehicle to capture the targeted vehicle's LED. The distance between the observed vehicles is determined by capturing images. The LED is easy to detect on the image, due to the high illumination and compact shape. Using such a system, the positioning information can be transmitted between vehicles.

Figure 3.

VLC based positioning can also be useful in tunnels, where GPS has poor performances. In such a system, LED lighting infrastructure in a tunnel and LED tail lamp in a vehicle have the absolute position coordinates. Location data are transmitted using VLC based V2V and V2I communication systems. It appears that three LED light sources on the tunnel infrastructure and vehicle tail lamps based on the image sensor can provide accurate positioning with approximately 1m error (Kim & Jung, 2016).

SOLUTIONS AND RECOMMENDATIONS

VLC applications in ITS are facing some technical issues and challenges that can limit the communication range. Relative mobility between vehicles or between infrastructure and vehicles can hinder the LOS. This issue can be tackled by optimizing lighting positioning. In addition, natural and artificial lights

add noise and interference, which can be minimized by using optical filters and optimized electronics. Reliable communication is possible if the distance between a VLC transmitter and a VLC receiver is in the range of 40 - 50 m (Liu, Sadeghi & Knightly, 2011).

VLC systems in vehicular communication need to fully support the mobility of the vehicles. Studies related to VLC connection between moving vehicles mostly analyze the scenario where the transmitter and the receiver are relatively aligned. However, in real traffic situations, the alignment between the transmitter and the receiver is not always satisfied. A possible solution for this challenge is to use more photodetectors oriented for different reception angles. Another possible solution is to implement more than one sensor on each side of the vehicle. Thus, at least one sensor can be properly aligned with the transmitter and the communication link can be established.

VLC can be a very promising solution for vehicle platooning, due to relatively short communication link requirements and the type of the transmitted data. However, the presence of ambient noise significantly affects platooning. Exchanged information about the relative position and front and rear facing directions of each vehicle of the platoon can be processed in each vehicle controller (Abualhoul, Marouf, Shagdar & Nashashibi, 2014). In addition, it is possible to compensate the trajectories influence on the optical incidence and irradiance angles efficiently. Furthermore, the total optical path loss between any two members of the platoon is reduced.

In vehicular VLC systems, it is very important to achieve high data rates with respect to lighting quality and its correlation with dimming utility (Ucar, Turan, Ergen, Ozkasap & Ergen, 2016). This is crucial especially in night conditions when a high beam of headlights can create glare and cause temporary blindness of a driver. In order to avoid these unsafe situations, light sources should be arbitrarily dimmed. However, efficient dimming control is achievable at the expense of decreasing data rates. In addition, external weather conditions such as snow, rain and fog affect dimming. Therefore, efficient dimming functionality requires a compromise between illumination and communication. A comprehensive analysis of dimming techniques can contribute to traffic safety improvement and provides full control over the lighting output.

Compared to RF communication, multipath propagation in V2V VLC systems is negligible. The signal power of the multipath components is significantly reduced and these multipath components usually can be ignored. Furthermore, visual obstacles can block the propagation of multipath components. Hence, the characterization of V2V VLC channels comprises the path loss and the path loss variation over time (Cui, Wang & Tsai, 2014). The path loss depends on the distance between the transmitter and the receiver, the irradiance angle and the incidence angle. A major source of time variation of the received signal power is the mobility of the vehicle. The location of the tail lights of neighboring vehicles with respect to the receiving vehicle can be estimated using the video data from camera sensors mounted on vehicles. Knowing the estimated location parameters of a single image, the path loss of the link between the observed vehicles at that time instance can be estimated. This procedure can be performed in multiple series, thus determining the time function of the path loss. These data can be further used to characterize the channel fading due to vehicle mobility.

VLC has numerous advantages in vehicular applications. However, the establishment of LOS is a major disadvantage that limits performances. Since VLC and RF are complementary technologies, their integration can enhance mobility and increase the reliability of the connection. For instance, integration of VLC and Dedicated Short Range Communication (DSRC) technology can significantly improve performances in safety applications. DSRC is a mature technology that enables long-distance communication. However, VLC is not able to provide comparable communication ranges but has a huge potential in high traffic densities. Such heterogeneous networks in vehicular communications are considered as a promising solution for future vehicular networks.

FUTURE RESEARCH DIRECTIONS

Visible light communication has the potential to provide low-cost high-data rate communication with improved energy efficiency. However, there are some challenges and open issues that need to be considered in the near future in order to enable the widespread use of VLC in ITS. The main assumption in the techniques of achieving high data rates in VLC links is the presence of LOS, where the transmitter and the receiver have aligned the field of views. In practice, receiver movement and orientation changes are very often. Therefore, it is essential to develop methods that can provide high data rates even in the presence of the field of view misalignments. This task is very challenging and represents an important direction for future research. In addition, it is necessary to develop receivers that can support robustness to device movements and field of view misalignments. Such receivers should also run with low energy consumption. Besides the field of view alignment, another important issue is tackling the shadowing effects. Hence, new techniques that provide real-time adjustment depending on the changes in received signal power, due to the field of view misalignments and shadowing, need to be developed.

Flickering, i.e. the fluctuations in the brightness of the light, can have harmful effects on human health. If a data rate is slow, or idle period in the system is significantly longer compared to the period of data transmission, the flickering effect is more noticeable. Therefore, the modulation technique needs to be chosen appropriately, in order to avoid flickering. Designing a modulation technique for VLC systems that reduces flickering is a very challenging issue and requires a lot of research effort. The suitability of indoor modulation techniques for outdoor scenarios can also be a subject for future research directions. Another important open issue is dimming. Different levels of illuminance are required in different indoor and outdoor scenarios. The algorithms for dimming in VLC systems should be designed so that the requirements for illuminance in a given scenario are satisfied.

CONCLUSION

Visible light communication is an optical wireless communication technology which uses visible light as a communication medium. The VLC system provides highly direction communications in LOS scenarios in short range with high sensitivity to weather conditions and ambient noise. Main characteristics of VLC systems are the following: there is no health concern, there is no electromagnetic interference, it is license free and it can be easily integrated into the existing lighting infrastructure. LEDs are commonly used as transmitters in VLC, while the photodiodes and camera sensors are commonly used VLC receivers. Nowadays, vehicles are equipped with LED lightening due to their long life span, high resistance to vibration, high energy efficiency and better safety performance. Furthermore, VLC receivers are mounted in many vehicles as the front or rear camera for lane tracking and parking purposes. These advantages make VLC a promising solution for ITS applications.

KEY TERMS AND DEFINITIONS

Infrastructure-to-Vehicle (I2V) Communications: A segment of ITS mainly used for data transmission from roadside infrastructure to vehicles.

Intelligent Transportation Systems (ITS): A set of information and communication technologies applied to the transportation systems with the aim of providing a more efficient, sustainable, and safe transportation system.

Vehicle-to-Infrastructure (V2I) Communications: A segment of ITS mainly used for data transmission from vehicles to the roadside infrastructure.

Vehicle-to-Vehicle (V2V) Communications: A segment of ITS mainly used for data transmission between vehicles on the roadside.

Visible Light Communication (VLC): An optical wireless communication technology using visible light as a communication medium.

VLC Receiver: Device that receives information modulated in the visible light spectrum. Photodiodes and camera sensors are commonly used.

VLC Transmitter: Device that transmits information using visible light spectrum. LEDs are commonly used.

Section 8

Digital Media

Antecedents and Consequences of the Growing Popularity of Digital Consumption

Ritu Narang

University of Lucknow, India

Sonal Tiwari

University of Lucknow, India

INTRODUCTION

There is something addictive and enthralling about the world where everything is digital (Hoffman, Novak and Stein, 2012). Splurging a large amount of one's time online, executing more than one task simultaneously and acquainting with new technologies easily are all testimonies to the increasing digital nature of everyone's daily life. Hoffman et al. (2012) further stated that new media has become an inevitable part of consumer's daily life and routine. It is influencing, altering and transforming the way they communicate, work, play, read, write, watch, listen, retain, explore, browse, shop, collaborate, produce and create. Each of these actions in the post-digital era was quite different when compared to the pre-digital era. New media has completely revamped people's everyday lives. For majority of people now, logging in is the foremost thing in the morning even before getting up (Hoffman et al., 2012). Stone (2009) commented in his study that those days are gone when newspaper was the only source of distraction while having first meal of the day with family. Majority of people now have replaced newspaper with mobile phones, tablets, laptops and other technological devices during breakfast with the family which was once known as the family time. People may spend the day on their smartphones using various applications either to browse restaurants, book movie tickets, view television shows online, listen to music, shop online, play games or to keep track of their daily exercise (Hoffman et al, 2012). Technology is present and apparent in every aspect of people's daily lives. Now, they have become addicted and dependent on new media to such an extent that they may become restless and feel panic if their internet connection is down for even a short period of time (Hoffman et al, 2012).

Thus, seeing the growth rate in the new technology and consumption of the internet, the current chapter tries to explore the reasons for the growth of digital consumption and consequences due to its over consumption. Till date, majority of studies have focussed on the factors which lead to internet addiction in general (Griffiths, 1995; Beard, 2005; Young, 1998; Caplan, 2005; Kim, LaRose & Peng, 2006). However, aspects of digital consumption like online television, online games, etc. have not been explored much. Therefore, the chapter tries to bridge the gap by taking into account 'internet television', a significant area under digital consumption. The present chapter seeks to draw attention on the following aspects of digital consumption:

- It will elaborate upon the concept of digital consumption and its growing popularity.
- It will focus on the meaning of internet television and reasons behind its growth.
- It will throw some light on the behavioural and physiological consequences of internet television consumption.

DOI: 10.4018/978-1-7998-3479-3.ch073

- It will include a conceptual model and its implications followed by some recommendations, insights about future scope of the study and conclusion.

BACKGROUND

Digital Consumption: It's Growing Popularity

With proliferation of digital devices and increasing internet penetration, today's consumers are more connected than ever. The increase in internet penetration and information and communication technology has given rise to new distribution channels, making online presence a requisite condition for marketers to extend their geographical boundaries (Narang & Trivedi, 2016). Earlier, content was available only through few mediums such as print, radio and conventional television but now it is also available through numerous multiple connected devices. This has revolutionised the media world and obscured traditional media definitions (Nielsen, 2014). The internet is widely used these days, with more than 3.75 billion people online today (Digital in report, 2017). Internet use continues to grow all over the world, with global users rising at the rate of 8 per cent per year. Today, nearly two-third of the world's population use smartphone and majority of the world's web traffic comes from smartphones. There are around 4.92 billion people across the globe that uses mobile phones which is equal to 66 per cent penetration (Digital in report, 2017).

Billions of people throughout the length of the day are continuously engrossed in the consumption of the internet, social media, mobile applications and other digital communication technologies (Stephen, 2015). This digital nature of people can be observed by looking at the time they are spending on the internet and the way they are embracing new technology (Belk and Liams, 2013). For instance, the internet usage rate among Americans is close to 87 per cent (Pew Research Center, 2015). Majority of people now have smartphones, high-definition televisions, computers, laptops, wi-fi networks due to which they are spending on an average of 60 hours per week on the consumption of content across various platforms or screens (Nielsen, 2014). In India, around 180 million people view online videos through YouTube on mobile alone (Chaturvedi, 2017). According to State of digital downloads research report (2017), over 62 per cent of European respondents prefer to download or watch TV shows and movies online. France has witnessed the highest streaming rate i.e. 49 per cent when compared to the UK and Germany who have witnessed 42 and 40 per cent respectively. Around 37 per cent of German consumers, 36 per cent of UK consumers and 30 per cent of French consumers prefer to download books and magazines. Similarly, 34 per cent of Germany and UK consumers choose to download music, on the other hand 56 per cent of French consumers more likely to stream music. In fact, social media has witnessed tremendous growth worldwide; more than 2 billion people are using it among which Facebook alone has 1 billion active users per day (Stephen, 2015). Nowadays social media usage has become an inevitable practice in consumers' daily lives. The number of social media users across the globe grew by more than 20 per cent over the past 12 months, with well over one-third of the world's population now using social media every month. Mobile social media use is growing even faster, with global monthly active user numbers up 30 per cent year-on-year to reach more than 2.5 billion (Digital in Report, 2017). Around 64 per cent of total social media users stated that they use these sites at least once a day through their computers and 47 per cent of smartphone owners stated that they spend time on these sites every day (Nielsen, 2014).

Initially, only the developed countries indulged in digital consumption but now even the developing countries are consuming it. As per the KPMG International Report (2013), people of China, Brazil and

Singapore are leading consumers of digital media and are consuming internet at a substantial pace. In fact, consumers of these countries are also ready to pay for the consumption of digital media. 78 per cent of Chinese consumers own a smartphone which showcases higher penetration as compared to the US, UK, Australia and Germany. With 140 million internet users Brazil has become the largest internet market in Latin America and fourth largest across the globe (Dossier, 2016). In South Korea, which is one of the most digitally advanced countries across the world, government reckoned that around 2.55 million people are addicted to their smartphones by consuming it for more than 8 hours per day (Yeomans, 2013). In India, there are around 3 lakh app developers and the country has already become second largest android developer community in the world (Deloitte, 2015). In 2014, smartphones users went beyond 2 billion and are forecasted to touch 4.6 billion mark by 2019 (Deloitte, 2015). The EY (2016) anticipates Indian smartphone market to reach 520mn by 2020, which would make India emerge as one of the largest smart phone economies in the world. With the emergence of better networks, coverage and advanced technologies such as 3G and 4G, there is an immense rise in the data consumption across the globe and it is quite evident in India with the launch of Jio by Reliance in the year 2016. Highest internet penetration is in countries like United Arab Emirates, Iceland, Norway, Luxembourg, Denmark, Bermuda, Andorra, Netherlands, Bahrain and Japan with 99 per cent, 98 per cent, 97 per cent, 96 per cent, 95 per cent and 93 per cent respectively (Digital in report, 2017).

Meaning of Internet Television

This section seeks to explore the meaning of Internet Television and reasons behind its growth. Internet television has different names such as personal TV, web TV, interactive TV, enhanced TV and so on (Gerbarg and Noam, 2004). According to Noll, (2004) internet television also known as online television is nothing but a traditional television which is now available on the internet. It is a video service that is available online which operates through website streaming in order to offer various television shows or videos (Schechner & Stewart, 2012). It is a streaming media through which people do not have to wait to download the video; instead, they can watch the television shows in real time as they are sent in a continuous stream of data and can be played as they are uploaded on the internet. Internet television has variously been defined as:

“Internet TV is an online video service that uses website streaming to offer TV programs or videos”
(Li, 2013, p.6)

“Online programming that makes media content available through a computer screen, tablet or speaker. It has the ability to displace or substantially supplement the use of non-computer media content”. (Ferguson, 2012, p. 143)

“Internet television is an internet subscription service that allows audiences to watch TV shows, movies, or videos via any digital devices via internet streaming”. (Schechner and Stewart, 2012, p. 9)

In this chapter, internet television refers to all those content which are produced primarily for viewing on the television set via cable or satellite, which is later made accessible online via various applications; content produced primarily for online distribution such as various web-series and user-generated content which can be produced by anybody and made available through YouTube.

REASONS FOR THE GROWTH OF INTERNET TELEVISION CONSUMPTION

There are several studies which have identified television viewing motivations and gratifications. Katz, Blumler and Gurevitch (1973) classify media consumption needs into five categories- Cognitive needs (understanding, knowledge and Information), Personal integrative needs (status, stability, confidence and credibility), Affective needs (emotional pleasurable or aesthetic experience), Social integrative needs (strengthening contacts with friends, family, etc.) and Tension release needs (diversion and escape). According to Greenberg (1974), there are seven motives behind television viewing- habit, relaxation, passing time, arousal, escape, companionship and learning. Palmgreen and Rayburn (1979) mention seven television viewing gratifications such as passing time, entertainment, relaxation, learning, forgetting, communication utility and companionship. Rubin (1981) determines nine television viewing motivations that include escape, companionship, passing time, habit, arousal, relaxation, entertainment, social interaction and information. Several studies have identified socio cognitive motives of television viewing. These motives were classified into two categories: positive and negative. Positive motives comprise of social engagement and enjoyment while, negative motives include boredom, escape from reality and finding solitude and solace among fictional TV characters (Farber, Khavari and Douglass, 1980; Cooper, 1994; Cooper et al. 1995; Lang et al. 2012 and Bailey and Baillie, 2013).

Ferguson and Perse (2000) postulate that motives like entertainment, relaxation and time pass are the same for both television and internet consumption and thus the internet may be functionally equivalent to television and can be treated as its substitute. Similarly, there are a few studies that also indicate that the motives for viewing television and internet television are identical such as information, escape, entertainment and social interaction (Ambra and Rice, 2001; Kaye, 1998; Lin 2001). On the contrary Li (2013) posits that motives of both the mediums are quite different. According to him, viewers attain three types of gratifications- content, process and social. Content gratification encompasses time pass, information and entertainment. Convenience and ease of use come under process gratification. Social gratification incorporates companionship and social interaction. In the opinion of Li (2013) process gratification is derived from the consumption of internet television and content gratification is obtained from television consumption. Harrell (2000) argues that internet users choose mass media in order to satisfy their information, companionship, escapism, communication and entertainment needs. According to Shin (2007), motives of internet television consumption can be divided into two: extrinsic and intrinsic. Extrinsic motives include highly interactive services and interoperable applications and intrinsic motives comprise of rich content, high quality videos and value added services.

Seeing the growth rate in the consumption of various digital platforms in various countries one becomes curious to explore the reasons behind this phenomenon. Some of the reasons are as follows:

Content

With the evolution of so many digital platforms, people are now able to consume different formats of media online such as movies, news, short form content, social interaction, gaming and education (EY, 2016). There is an increase in the inclination towards online content platforms. Multiple players in this sector are now offering personalised content in the form of web-series, videos and other digital programming options in order to generate the interest of their viewers and make their eyeballs glued to the digital screens. Viewers are now getting far more individualized experience due to the internet. Since so many shows are available online, computer screen has easily substituted television screen (Marshall, 2009).

Earlier, content was created in multiples of 30 minutes but with the emergence of on-demand viewing, people are no more interested in spending an hour or half-an-hour in front of their television screens. Nowadays, consumers, especially the younger lot are viewing more of short-form content whose average length is less than 20 minutes. According to the EY Report (2016, p 9), “62 per cent of the content consumed on YouTube is short-form content.” Due to this trend, content producers have now started to focus more on the production of short-form content. From this, it can be induced that today’s consumers are fascinated more by the story line and not its length.

Convenience

The option to watch several videos and TV shows anytime and anywhere gives rise to consumption of Internet Television. It means now viewers do not have to make themselves available at the time of broadcast in order to watch the latest episode of a favourite show. Internet viewers do not have to wait for the show to be aired instead they can watch them as per their own convenience. Due to this trend, more and more networks are now making their shows available online (Melton, 2013). Consumers or Audiences who have an option to skip, can catch their favourite shows on various digital platforms in case they miss it live on television. Usually, evening time is considered as a prime time for watching a television show but now they have an option to view a range of shows at any time during the day or night according to their convenience (Pena, 2015). According to a research conducted by comScore Inc., (2014) about 56 per cent of the US internet users stated that they prefer to watch television online because it gives them an opportunity to watch their favourite shows as per their own schedule. While 50 per cent of the users stated that they view television on internet because it is just more convenient.

With the advent of several sites and mobile applications such as Netflix, Amazon Prime, Hulu and many more has given a platform through which ample of television shows and videos can be accessed rapidly and inexpensively (Lee, 2013). The ever-increasing popularity of smartphones, tablets and laptops has led to a phenomenon known as “second screening” which means viewers are using internet connected gadgets in order to avail additional content be it watching any show or using social media handles. The best thing about viewing television on these internet-connected devices is that they are handy and mobile i.e. consumers can take these devices along with them irrespective of where they are heading. Viewers who prefer to watch online television on these devices are not restricted to view it only where their television is placed at home. They can view it at the gym, lunch breaks, while waiting in a queue or anywhere else (Melton, 2013).

According to a study conducted by the Online Publishers Association, (2004) two kind of lifestyles exist among the consumers who are aged between 18-34 years. These lifestyles can be categorised as “unsettled” and “newly settled”. Consumers who all are aged 18-24 years are likely to fall in the first category i.e. unsettled. They are the ones who do not have any predictable schedule or routine, for instance, a college student may choose to go to the gym one day while other day he might choose to socialize with friends. In general, these unsettled consumers do not follow a set schedule or a prescribed routine as compared to the consumers who are newly settled. Thus, as a result, convenience and accessibility play a key role in swaying media use. The study further stated that various media serve different functions like television is treated as a source of escape and entertainment while radio is treated as a source of companionship and connectedness and web or the internet is a source of information and described as convenient and accessible.

Binge Watching

The tendency of viewers to be hooked to online television is known as ‘binge watching’. It is also known as ‘marathon viewing’ and is a recent behaviour which is found among the consumers these days. It means “viewing multiple episodes of a particular show or series over a concentrated period of time” (Pena, 2015). This recent television behaviour allows consumers to view their favourite show all at once at their convenience (Sodano, 2012). Horsey (2013), stated that there is no such thing as missing a show in this new era of television. VCRs which were used earlier went digital and turned into DVR which made it possible for consumers to record their favourite show and watch it later on (Chmielewski, 2013). Soon after, with the further advancement of digital services, such as, Netflix, Amazon Prime, Hulu and video on demand, the habit to consume all the episodes of a show at one go has been elevated (Umstead, 2014). A consumer can indulge into binge watching whenever and wherever he or she wants. He or she can spend his or her summer break by watching movies without a break or the complete season of his or her favourite show while fighting the flu (Pena, 2015).

Pena, (2015) found in a survey that people do not indulge in binge watching intentionally. Around 71 per cent of binge watchers claimed that initially they did not intend to watch more than one or two episodes but once they started watching it, they ended up watching more episodes. A 2013 survey conducted by MarketCast unveiled that around 67 per cent of American television viewers who are aged between 13-49 years old, are engrossed in binge watching. A survey done by TiVo, (2014) revealed that 91 per cent of its subscribers see binge viewing as a common viewing behaviour. These figures are likely to increase more with the launch of various technology devices and television content which are now easily available to consumers. The services such as Hulu, Amazon Prime, Netflix, HBO Go, HotStar and many more are constantly devoted to making binge viewing convenient to consumers and remunerative to business (Pena, 2015).

Control

Gone are the days when viewership norms were based on mass appeal, finite shows on set schedules, few genres and limited access and control by the consumers. The television industry was dominated by very few networks, offering unique shows, uniform programming and availability, which compelled audiences to settle for the same, the only option they had was either to watch it in daytime or prime-time (Lotz, 2007). Networks competed with each other for securing prime time slots and kept the viewers on the hook by ending each episode with suspense afford to miss (Barker, 2011). It was the time when television was known as “appointment television” where audiences used to make themselves available by altering their schedules so that they could watch their favourite shows at the scheduled time (Pena, 2015).

Appointment television basically refers to the popular shows that people make a point to remember to watch. Now with the expansion of technology, television has moved to the internet and does not remain time-constricted, thus lifespan of appointment television is now uncertain. Internet television has challenged the perception that viewers would still permit the cable channels and networks to tell them ‘what’ and ‘when’ to watch (Zurawik, 2013). Steinkamp, (2010) conducted a survey and stated that out of 136 respondents, 70 vehemently agreed and 41 agreed that Internet Television enables them “to choose when to watch my favourite TV program”.

Internet has devastated the television industry, but not the television. Television still is treated as a platform which has a power to bring people together by making them watch their favourite shows and getting them invest in its storyline and characters. Viewers still are longing to know what happens to

their favourite character in the show. The only thing which has changed now is that they want to know it at a time that suits them and not the network (Montpetit, 2014).

Skip Commercials

Skipping commercials is one of a few added perks which viewers receive while watching television online. Viewers get an option to skip commercials and enjoy watching their favourite television shows online without any disturbance. Consumers always try to find ways to avoid commercials or advertisements. This is why most of the consumers end up purchasing ad-free subscription services some of which are Amazon Prime and Netflix so that they can zip through the advertisements (James and Battaglio, 2017). Steinkamp (2010), conducted a survey in which one of the respondents stated that it's quite annoying whenever commercials pop up while he/she is watching a show. At least with online television they get an option to skip commercials and even if they won't get this option then in that case they only have to view these ads for 30 seconds max. Another respondent stated that nowadays, television commercials are becoming longer and more obnoxious and he was of the opinion that shows with fewer commercials were better.

Consequences of Internet Television Consumption

This section throws some light on the consequences or effects of post digital consumption on its users. In the present scenario, smartphones have become our constant companion: WhatsApp and Facebook for connecting with friends, Netflix for watching movies and shows, etc. Some consumers use their smartphones so many times in a day that soon they start generating this feeling that they cannot live without it. New media when consumed excessively may lead to addiction. It was Marks, (1990) who put forth the concept of media addiction. According to him, there is an analogy between media addiction and psychiatric conditions with dependency or compulsive qualities or a sort of obsession, and the criteria to diagnose those conditions were accordingly adjusted to media consumption behaviour.

An American psychologist, Goldberg, (1996) evolved a new concept known as internet addiction. According to him, internet addiction is a process of reducing stress, but excessive addiction might result in weakening the mental and physical function of a user's career, social nature and relationship with family. Few studies (Young, 1996; Greenfield & Davis, 2002) have compared media addiction to the term 'impulse control disorder' and have clarified that it does include an inebriant characteristic. Kandell, (1998) defined media addiction as a psychological habituation of media and according to Griffiths, (2000) it is a technological addiction and a subgroup of behavioural addiction. Many researchers have identified different terms for media addiction such as 'unregulated media use' (LaRose, Lin & Eastin, 2003), 'media dependence' (Yuen & Lavin, 2004), 'compulsive media use' (Meerkerk, Eijnden & Garretsen, 2006), 'problematic media use' (Caplan, 2002, 2010; Davis, Flett & Avibesser, 2002) and 'excessive media use' (Suhail & Bargees, 2006). According to Kalus (2016), addiction develops in five stages:

- **Trying:** Addiction begins with the trying of new things. For instance, playing a new game, watching a new show, etc.
- **Enjoyment:** When a person is delighted by using a new media application.
- **Habituation:** When a person inculcate a habit of using new media application.
- **Misuse:** When media consumption goes beyond normal consumption.
- **Addiction:** When a person starts neglecting his or her work, family, friends, daily hobbies in order to use this application.

Needless to say, consumers have to witness certain consequences or implications whenever they consume anything in excess and internet is no exception. According to Xu, *et. al.* (2018), health does not merely mean absence of disease but it comprises of physical, mental and social well-being. Physical health allows individuals to perform their routine activities without any restrictions. Mental health deals with a state of well-being in which the individual realises his or her own abilities and can work productively and fruitfully. Social health refers to an individual's ability to manage in social situations and behave accordingly. In this chapter, consequences have been divided into two- physiological and behavioural. Physiological consequences comprise of physical health and behavioural consequences deal with mental and social health. The consequences are as follows:

Physiological Consequences

Wang et al, (2015) stated that excessive use of smartphones lead to depression, sleep disorder and psychological discomfort. According to Young, (1998) some physical problems were faced by the people due to over consumption of internet such as poor immunity system, fatigue and lack of sleep. Brenner, (1997) conducted an online survey on the internet usage and came to the conclusion that people who spend more time on the internet are more likely to face several problems such as missing meals, lack of time management, lack of sleep, etc. People who are internet addicted tend to suffer from physical symptoms such as insomnia, fatigue, exhaustion, poor eyesight, appetite problems, weight loss, weight gain (due to physical inactivity), agitation, backache, neck pain and arms pain (Lan and Lee, 2013).

Behavioural Consequences

The use of several personal devices such as mobile phones, laptops, tablets, etc. to view various shows, movies and other videos lead to “personal escapism” which means viewing content individually and not with the family (EY, 2016). This trend might change the type of content consumed by the viewers. Viewers come across to many shows, movies or games that consist of violence, which in turn can influence their behaviour. According to Funk (2004), Violence in entertainment media acts as a contributor to violent and aggressive behaviour in real life. Farrell and Bruce, (1997) conducted a survey on students in order to ascertain the impact of violence exposure on the level of their aggression and distress. They concluded that there was a significant relation between violence exposure and aggression. Farrell and Bruce suggested that children who view things which consist of violence become desensitized to violence, which increases aggression. Media presentations of justified violence may change a person's belief that violent behaviour is undesirable and wrong. This change in one's belief might promote pro violence attitudes (Funk, 2004). Anderson and Dill, (2000) differentiate between short-term and long-term effects of violence shown in video games on consumers. Short-term effects of video game are concerned with the present internal state of a person. Whenever a person is exposed to violent media, it gives rise to aggressive thoughts, negative feelings or increase in arousal. Long-term effects may result “in the development, over-learning and reinforcement of aggression-related knowledge structures” (p-9). These knowledge structures consist of aggressive action against others; conjecture that other people will behave aggressively, positive attitude towards use of violence and the belief that violent solutions which are derived through a violent action are acceptable and effective. According to Gentile, (2000) the more the students are exposed to violent media, the more they indulge in physical fights and arguments with teachers.

Some internet users stated that they are witnessing quite serious consequences such as becoming socially isolated or getting into trouble with their boss (Brenner, 1997). According to Kubey & Csikszentmihalyi (2002), people who are addicted to television are less likely to engage in sports and other community activities. Few researchers argued that television addiction hampers one's ability to function at work and home (Meerlo, 1954; Sjoberg & Magneberg, 2007). People tend to give up their social, recreational and occupational activities for instance, one may start ignoring their jobs or family duties or prosocial hobbies (McIlwraith, 1998). According to Cao & Su (2007), people with an internet addiction tend to experience greater mental illness than those not addicted. Bandura, (1986, 1991, p. 232) defined deficient self-regulation of internet use as *"a state in which conscious self-control is relatively diminished"* It particularly means when a person fails to monitor his consumption or usage behaviour. Consequently, deficient self-regulation of one's internet use may impact one's professional life and personal relationships adversely (Caplan, 2010). According to Harris and Williams, (1985) students who invest more time and money on playing video games tend to score poor grades in school. The content of the games and shows or movies which students play and watch respectively may hamper their school performances. For instance, if a student is investing more of his time on educational games and shows then he would probably be less likely to show a poor school performance. According to Lieberman et al. (1988) children who use computers in order to play more games, tend to perform more poorly in school. On the other hand, children who use computers for school work, perform better. Gentile, (2004) stated that if children spend more time on playing games rather than on educational and social activities, then, in that case, their grades are affected negatively. Following this logic, it could be inferred that electronic media can impact a person's learning and social behaviour by replacing other activities such as family interaction, reading and social life with peers and friends (Huston, et al., 1992). Young, (1998) classified the problems associated with internet addiction under five categories: relationship, occupational, academic, physical and financial. According to him, excessive use of the internet can have an adverse impact on friendships, parent-child relationships, and husband-wife relationships because they are likely to spend less time with their family and friends. Using internet for personal work at the working hours can have a negative impact on one's productivity which in turn, can result in losing job. Students face academic related problems, when at the time of study they indulge in chatting with friends and exploring immaterial sites.

Shatton (1991) is the one who explored the positive effects of computer addiction. He stated that individuals who overuse computers are likely to gain some benefits from it like people end up exploring improved job offers due to elevation in their analytical, reasoning and technical skills. This knowledge has a positive impact on their confidence and self-esteem. People are able to communicate in an effective manner because of the knowledge they have gained and it has also helped them to expand their friends circle and have an impressive social life. People have gained respect through their expertise in technology and many dependants derived pleasure by giving advice to those ones who were not experienced/well-versed with the new technology Usage of computers has resulted into gaining a sense of achievement and satisfaction which in turn has helped people to relieve them from depression, stress and boredom (Shatton, 1991).

CONCEPTUAL MODEL

Based on the extensive literature review and the observations gained therein, this chapter has proposed a conceptual model to extend knowledge about antecedents and consequences of internet television

Figure 1. Antecedents and Consequences of Internet television consumption

consumption. The proposed conceptual model provides insight into what motivates viewers to consume internet television and consequences that they face due to its overconsumption. Figure 1 illustrates the three main parts namely, A, B and C of the model. Part A deals with the antecedents of internet television consumption, Part B talks about how excessive consumption leads to technology addiction and Part C explains the consequences of technology addiction.

Part A talks about antecedents of internet television, namely content, convenience, control, binge watching and skip commercials.

Content: With content, the researchers mean the storyline, time duration, picturisation and number of episodes of the shows available on several video streaming portals. The demand of internet television increases due to the ‘quality of content’ which these video streaming portals are offering to its viewers (Marshal, 2009 and EY Report, 2016). People get shows of different genres on these portals. Unlike television, there is an unlimited pool of shows available on the internet among which viewers can watch any show of their choice. Furthermore, the quality of actors, story and picturisation of internet shows are far better than the shows available on television. These shows have limited number of episodes and are of shorter duration unlike shows which are available on conventional television. Thus, the availability of good quality content provides further impetus to growth of internet television.

Convenience: Convenience means something that makes things easier, comfortable and more suitable for people (Narang & Trivedi, 2016). One of the reasons for increase in internet television consumption might be its convenient nature. Due to online television, consumers get flexibility of watching what they want at their convenience. People can view internet television anytime and anywhere. Since internet television can be watched on smart phones and laptops, it becomes quite handy and mobile for viewers to see their favourite shows and thus, viewers now do not have to sit at one place on a scheduled time in order to watch television.

Binge watching: Binge watching means viewing episodes of a show one after the other. On the video streaming portals, viewers have an opportunity to watch their favourite shows in one go since all the episodes are available on it and with the availability of internet television, people do not have to wait for the next episode to be aired on television. According to Pena (2015), a consumer can indulge in binge watching whenever and wherever he or she wants due to the availability of all the episodes of his or her favourite shows. Thus, the simultaneous availability of all the episodes on internet might lead to consumption of shows on video streaming portals.

Control: Control refers to an act of ruling something or someone. One of the major reasons viewers might prefer to watch shows online is the power to enjoy control. Today's youth want to be entertained with content made for them to be consumed on devices, time and place of their choice (Bansal, 2018). With the emergence of several video streaming portals, people are not controlled by the cable channels and networks anymore. It is now the consumers who decide 'what' to watch, 'when' to watch, 'where' to watch and on 'which' device to watch their favourite shows, thereby giving absolute dominance in the hands of the viewers.

Skip commercials: Skip commercials refer to a feature that makes it possible for viewers to watch shows without advertisements or commercials. This feature helps in making shows commercial free. People might also choose to watch internet television because shows which are available on the internet are either commercial free or commercials are of maximum 30 seconds which they can easily skip. People do not like to get disturbed while watching something of their interest. These commercials act as a disturbance that could be a reason why people prefer watching shows on the internet and not on conventional television.

Part B talks about excessive use of internet television which might result in addiction on the part of the viewers. Addiction develops in five stages: trying, enjoyment, habituation, misuse and addiction (Kalus, 2016). Initially, people try video streaming portals because of the antecedents mentioned above. Soon they start enjoying the same because of the perks which they get through these shows such as quality of content, power to control, its convenient nature, availability of all the episodes and the option to skip commercials. Then, it becomes their habit and they start consuming it beyond a certain limit and once they over-consume it, they become addicted to it. As stated by Xue, Dong, Luo, Mo, Dong, Zhang and Liang (2018), excessive use of the services can lead to technology addiction.

Users who are technology addicted might experience negative consequences such as physiological and behavioural as explained in Part C of the model. Physiological consequences such as fatigue, lack of sleep, missing meals, lack of time management (Brenner, 1997; Young, 1998; Wang *et. al.* 2015) deal with the physical health of an individual i.e., all internal and external organs and body parts of a person are functioning properly as they are supposed to function. When a person becomes addicted to these video streaming portals and watches shows at night for a longer period of time, they tend to become sleep deprived. Due to lack of proper sleep they are likely to feel drowsy during the day. Behavioural consequences like personal escapism, aggression, violence, social-isolation, poor performance, relationship and occupation related problems, etc. (Harris and Williams, 1985; Brenner, 1997; Young, 1998; Gentile, 2000) deal with the social and mental health of an individual i.e., how a person is behaving in social situations and is he/she able to cope with the normal stresses of life. However, internet television has not only revamped consumers' way of viewing television but also provided certain benefits to its consumers such as gaining expertise in technology, improved communication skills, impressive social life, increase in confidence and self-esteem and relieve from depression, stress and boredom (Shatton, 1991).

IMPLICATIONS OF THE MODEL AND RECOMMENDATIONS

Video streaming portals form an important part of our everyday lives now. Consumers find themselves discovering new shows and binge watching them till they have finally completed a “season”-sometimes in a single night. It rescues them from boredom, exposes them to a new kind of culture and sometimes acts as a topic over which people bond. The shows available online are highly engaging and leave people craving to watch one episode after the other.

No doubt, one cannot ignore the popularity of this new media because they are the source of entertainment. However, this model seeks to bring attention towards negative consequences that might arise due to its excessive consumption. As it is rightly said that *‘there is no rose without a thorn’* similarly, its over-consumption might have some serious impact on viewers. Late night binge watching leads to lack of sleep which might affect an individual’s capacity to work, productivity and concentration level at work, school or colleges. The excitement of “what happens next” in the series might promote people to finish their work as soon as possible without actually paying attention to its quality. Sometimes, they may even procrastinate. Students may find themselves compromising on their studies just to finish a ‘season’ before their peers do.

People who prefer watching shows at night and for longer period are likely to experience mood swings and lower tolerance levels due to lack of proper sleep hence, might become more irritated and aggressive which will further disrupt their personal and professional lives which will ultimately affect the society as well as the economy of the nation. Movies and TV shows have always had an impact on people’s lifestyles-the way they dress up, talk, the kind of jargons they use, the kind of romantic involvements they expect, etc. (Bleakley & Ellithorpe, 2016). There is not a single sphere of life which has not been influenced by the kind of movies and shows people watch. Many researchers have pointed out how early exposure to violent TV shows results in higher levels of anxiety and aggression in children (Farrell & Bruce, 1997, Anderson & Dill, 2000 & Funk, 2004). These studies may have focussed more on children but same might be applied to youngsters also. Youth tend to look for role models in their favourite shows and replicate their actions. If these characters are too violent, aggressive and villainous, they are likely to absent mindedly copy their acts in their peer groups. Their young minds are likely to get negatively influenced and are unable to distinguish right from wrong. Some of the content is so violent that it can render even the adults sleepless.

The model emphasises the need to pay attention to the negative consequences of watching shows on video streaming portals. Family, teachers, media, government, and society can play an important role to reduce the impact of over-consumption on viewers. Government should encourage the development of certain applications which can monitor viewers’ screen time or applications that can lock these video streaming portals for a specified time once it exceeds a certain limit. However, maintaining a disciplined lifestyle and understanding the harmful impact of spending a lot of time watching can be instrumental in controlling this habit. It is also suggested that parents and teachers should monitor the content their children or students are exposed to, also the censor boards should assume a more responsible role in order to see whether the content going on air is refined and not too disturbingly violent in nature. Therefore, only if media is consumed in a proper manner and within limits, it can have positive implications else it could lead to negative implications on an individual as well as the society.

FUTURE RESEARCH DIRECTIONS

Future research can be conducted to empirically test the reasons behind growing popularity of internet television. This chapter has not explored certain other aspects and features associated with internet television such as buffering speed, downloading time, prices, etc. Further studies can also throw some light on the consequences other than the ones which are mentioned in this chapter such as psychological consequences, financial consequences, etc.

CONCLUSION

The objective of the chapter was to explore the following aspects of digital consumption: 1) The concept of digital consumption and its growing popularity. 2) The meaning of internet television and reasons behind its growth. 3) Consequences of internet television consumption. 4) A conceptual model based on antecedents and consequences of internet television consumption. Viewers consume internet television due to its convenient nature, quality of content, control, opportunity to binge watch and option to skip commercials. Thus, the growth rate witnessed by internet television across the globe promises to transform the way consumers or viewers used to watch television in the pre-digital era. The new media technology has not only induced the lifestyle patterns of consumers but also has created a modern culture by swaying the way people communicate, learn, behave and perceive themselves and the world in which they are living. However, if it consumed excessively then the consumers tend to suffer from certain physiological and behavioural consequences.

KEY TERMS AND DEFINITIONS

Binge Watching: Binge watching means viewing episodes of a show one after the other.

Content: It refers to the storyline, time duration, picturisation, and number of episodes of the shows available on several video streaming portals.

Control: Control refers to an act of ruling something or someone.

Convenience: Convenience means something that makes things easier, comfortable, and more suitable for people.

Digital Consumption: It refers to the sum of entertainment and information media consumed by an individual.

Internet Addiction: It is defined as a compulsive behaviour which makes an individual dependent and disrupts one's professional and personal life.

Internet Television: It refers to all those content which are produced primarily for viewing on the television set via cable or satellite, which is later made accessible online via various applications; content produced primarily for online distribution such as various web-series and user-generated content which can be produced by anybody and made available through YouTube.

Skip Commercials: Skip commercials refer to a feature that makes it possible for viewers to watch shows without advertisements or commercials.

Video Streaming Portals: It refers to a platform or application on which several television shows, series, movies, and videos are available.

Television Use and Consumption of Elderly Americans

8

INTRODUCTION

While parents, educators, and media critics have done much hand-wringing over the potential effects of modern television on today's youth (Domingues-Montanari, 2017), research suggests that the oldest among us might be more at risk when it comes to troubling screen time; the elderly watch more TV and benefit less from it than younger people (Depp, Schkade, Thompson, & Jeste, 2010). Thus, the purpose of the present research is to offer insight into how the elderly in the United States use, consume, and are affected by television, both in traditional legacy media settings and in newer digital media formats. This entry begins with background information, including definitions and a discussion of the changes in modern television consumption. Next, TV use by senior citizens and the potential effects of that use is discussed. Finally, solutions, recommendations, and potential future research avenues are offered.

BACKGROUND

The focus of this encyclopedia entry is to understand the impact of television consumption on the elderly population. With the advent of digital technologies impacting and transforming how we consumer media it becomes imperative to clearly define the two main concepts of this chapter. For the purposes of this study, the following terms are defined as indicated:

Elderly population: The term “elderly” can have different meanings depending on the source (Weeks, 2013) with the origination of the word coming from the word “elder” and generally means old (Online Etymology Dictionary, n.d.). The United States Social Security office considers people over the age of 66 eligible for full retirement with full benefits (Borland, 2017). However, most of the research presented here focused on this population seems to reference people over the age of 60 (e.g. Fouts, 1989 or Eggermont & Vandebosch, 2001) as being part of the “aging” population. This population is of particular importance because it is an under-researched growing population. The U.S. Census Bureau as cited in the Population Reference Bureau (2015) projects the number of Americans aged 65 and older is projected to double to 95 million by 2060 - sharing nearly a quarter of the population (Mather, Scommegna, & Kilduff, 2015).

Television Consumption: With nearly 80% of Americans watching some form of television on a daily basis and it is considered “America’s favorite pastime.” For the purpose of this study, the American

DOI: 10.4018/978-1-7998-3479-3.ch074

Time Use Survey (ATUS) from the United States Bureau of Labor Statistics (BLS) defines “watching TV” as the definition of television consumption, “As defined in the ATUS, “watching TV” refers to any time people said their main activity involved watching TV, videos, or movies. This includes the time they spent watching live programming, viewing DVDs, and streaming shows on their TV sets, computers, and portable devices. It does not include time spent viewing movies at a theater” (Krantz-Kent, 2018).

The Changing Landscape of Traditional Television Viewing

Television consumption, as with most media consumption, has changed drastically in the last 20 years (Einav & Wolf, 2019). Internet use has shown to cut into television time, particularly for the most experienced internet users (Cole, 2003). Younger audiences, those born in 1980 and after, are driving these changes, as they expect more options as well as a more personalized media consumption experience (Einav & Wolf, 2019). Almost half of all adults, 22-45 years old, are not watching traditional TV (Poggi, 2017). What has developed is a new age of “cord cutters,” those who end their pay TV subscription from cable and satellite, and “cord nevers,” those who never paid for those services to begin with and never intend to. These two groups are also responsible for the rise in over-the-top (OTT) television services, TV delivered via the internet through online services such as Netflix and Hulu (Einav & Wolf, 2019, para. 19-20). By 2017, according to Parks Associates, 69 percent of U.S. broadband households were OTT subscribers, with more than half paying for more than one service. This trend is expected to continue as about 75% of all TV households in the U.S. have a connected device, with the average household having 3.9 connected devices (Frankel, 2019).

Content providers for streaming services have exploded in recent years as well. Netflix is probably best known for originally delivering movies to homes via mail to today becoming a powerful streaming service. In fact, some even reference “the Netflix Effect” as being when a new series catapults the fame of a program or actor overnight (Morgan, 2019). The sharable nature of the availability of this content creates accelerated viewing and popularity like nothing seen in the past. In addition to Netflix and Hulu, the market is flooded with previous cable channel content providers (TBS, TNT, CNN) and premium content providers such as HBO – each creating streaming applications and online portals. For example, a recent acquisition of Time Warner by AT&T has created a new company called WarnerMedia, aimed to compete with the likes of Netflix (Sims, 2019). Just as the devices have changed so has the production and distribution of content. These changes will undoubtedly continue for the foreseeable future as digital technology continues to evolve.

TELEVISION CONSUMPTION TRENDS OF ELDERLY AMERICANS

Despite the hype of digital, networked, and mobile technology, television is still the most voracious consumer of time for older Americans. Research suggests that as people age, their consumption of television increases. This is particularly true among senior citizens, who rely on TV more than any other form of media (Fouts, 1989; Nielsen, 2014). In fact, the average American over 65 spent 30 more minutes per day watching television when compared to the year 2003 (Kopf, 2019). According to the Bureau of Labor Statistics (2018), of all age groups, older Americans spend the most time watching television. Trending from 2013-2017, the average hours per day watching television for 55-64 years of age was 2.9 hours per day. Americans over the age of 65 spent an hour more watching an average of 4.1 hours per day while those over the age of 75 watch an average of 4.5 hours per day. This trended significantly

higher one year later with those 65+ watching an average of 6 hours and 51 minutes per day as measured in the third quarter of 2018 (Marketing Charts, 2019). Comparatively, Americans average just under two hours per day across all age breaks under 45 years old. The power of television is profound with Americans over the age of 65 spending more time watching TV than reading, socializing, relaxing and all other leisure activities combined. There is no doubt senior citizens and those approaching senior citizen status account for a large percent of the television viewing audience. The most popular television show for the last five years, as of 2014, has been CBS's NCIS, a military-based police procedural, which has a median viewer age of 60 (Kang, 2014).

In today's digital media environment, time-shifting television has become the norm with cable, satellite, and streaming services allowing viewers to watch "on demand" and "binge" on consecutive programs in a series. Streaming (time-shifting) is on the increase with all television viewers but elderly viewers are beginning to participate in the trend. In 2017, a study by Wall Street investment bank Barclays found viewing on OTT sources such as an internet-connected smart TV or device has increased 45% among 55-64 year olds and increased by 36% among those over the age of 65 (Kiger, 2017). However, as of 2017, almost half of people 65 and up still do not have broadband. And the tech gap is exaggerated for those who are entering older age at 65 and those who are 75 and older. For broadband, 66 percent of people 65 to 69 years old are subscribers. That compares to only 41 percent for ages 75 to 79 and a mere 28 percent for ages 80 and older. For smartphones, 59 percent of people 65 to 69 had a smartphone. That compares to only 31 percent for ages 75 to 79 and a paltry 17 percent for people 80 and older (Anderson & Perrin, 2017). OTT and digital media will continue to elude the majority of the oldest Americans until those adoption rates are improved. And while the internet does have the potential to cut into television time (Cole, 2003), the oldest are the least likely to be connected, with only 44 percent of people 80 and up using the internet (Anderson & Perrin, 2017).

Television and News

Television news has historically been a powerhouse for informing the public and for decades, prior to internet, lead in "breaking" news and coverage of live events. However, the internet and digital media has vastly changed how the American public is informed – with the exception of elderly Americans. The Pew Research Center (2016) reported most people age 65 and older (85%) turn to television for their news with only 48% stating they get their news from newspapers. When comparing television news by age, the data shows a stark difference in age with 27% of 18-29 year olds and 45% of 30-49 year olds "often" getting their news from television. The digital divide among generations can be illustrated with nearly 50% of 18-49 year olds "often" getting their news online compared to only 20% Americans 65 and over. Thus, television serves as a vital link between seniors and information about the world around them.

When comparing news consumption across news outlets such as local, national network (i.e. CBS, NBC, etc.), and cable, elderly Americans are still consuming the most as well. Only 18% of 18-29 year olds get their news from local television compared to 57% of those aged 65+. In a similar fashion, elderly Americans are "often" getting their news from network news (49%) and cable news (58%) compared to 18-29 year olds often getting their news with 8% of network news and 10% of cable news, respectfully.

Television and Quality Perceptions

Given the amount of time seniors spend with TV, one would think they find great enjoyment from the pastime. However, research by Depp, Schkade, Thompson, and Jeste (2010) contradicts such a deduc-

tion. According to their study, adults 65 and up do indeed watch more TV, but enjoy it significantly less than their younger counterparts. Older adults did not receive the stress-reduction benefits of television consumption compared to their younger counterparts. Moreover, television consumption among older adults coincided with greater sadness. The authors speculated that seniors might watch TV more because they have more free time and because it is an easy and accessible activity when compared to others, such as exercise. They also suggested that TV consumption by older adults could be related to habitual/addictive cycles, use despite a diminishment of returns. In a similar vein, researchers found that older people who watch more television reported greater dissatisfaction with their own lives. This finding was attributed to a possible disconnect between the viewer's financial status versus the wealth, riches, and material possessions the viewer sees on TV (Rahtz, Sirgy, & Meadow, 1988).

Given the great amount of time that elderly adults spend with television, there is an understandable concern about the effects that medium has on them. Vickers (2007) argued that, historically, the portrayal of older Americans on TV has not been positive. She suggested that the skew toward younger talent and storylines that appeal to younger audiences effectively tells older audiences that they are not valued in the media landscape. She also noted that the recent focus on anti-aging cosmetics and surgery is also troublesome. She pointed to research that showed that the more seniors watch TV, the less positive they are about growing old.

EFFECTS OF TV ON THE ELDERLY

Health Impact of Television on the Elderly

Activity is understood to be a part of a healthy lifestyle, but for the elderly, being active can become more and more challenging with age. Inoue et al. (2012) found that people who watched less television were also less likely to be overweight or obese, a finding that coincides with television viewing as contributing to a sedentary lifestyle.

In particular, [sedentary behavior (SB)], or proxy measures such as television viewing, have been shown to be associated with an increased risk of obesity, cancer, metabolic syndrome, type 2 diabetes, and all-cause mortality in various populations. There has been very limited research focusing on adults aged ≥65 years despite evidence to suggest older adults represent the most sedentary age group, spending approximately 60% to 70% of their waking hours in SB. (Gennuso, Gangnon, Matthews, Thraen-Borowski, & Colbert, 2013, para. 5)

In fact, that is exactly what research from de Rezende, Rey-López, Matsudo, & do Carmo Luiz (2014) showed. The researchers found that the elderly spend the majority of their day participating in sedentary activities, such as watching television. And that sedentary lifestyle, the researchers found, is related to a greater risk in mortality in older adults.

Physical Limitations

Watching television is traditionally a sedentary activity and with the elderly, mobility can become problematic. A study by DiPietro, Jin, Talegawkar and Matthews (2018) looked at the association between sedentary time and physical activity with mobility. Analyzing data from 134,269 people in the National

Institutes of Health (NIH)-American Association of Retired Persons (NIH-AARP) Diet and Health Study, the researchers found a reduction in sedentary time combined with an increase in physical activity can lead to or at least maintain mobility function in older age. The study found, “Within all levels of physical activity, increasing amounts of TV time increased the odds of mobility disability in a dose–response manner, with almost a curvilinear accelerated odds of disability observed with increasing TV time in combination with the lowest levels of physical activity” (para. 14). A study done outside of the United States found older adults who watched less television were less likely to be overweight or obese independent of their participation in moderate-to-vigorous physical activity (Inoue et al., 2012). Reed et al. (2017) conducted a 12-year television viewing study examining performance-based measures of physical function concluding patterns of sedentary behavior can be a determinant of muscle strength in later life.

Dementia

According to an international study by Fancourt and Steptoe (2019), watching too much television can increase the likelihood of dementia.

Dementia is an overall term for diseases and conditions characterized by a decline in memory, language, problem-solving and other thinking skills that affect a person’s ability to perform everyday activities. Memory loss is an example. Alzheimer’s is the most common cause of dementia. (Alzheimer’s Association, 2019, para. 1)

Using data from the *English Longitudinal Study of Aging*, longitudinal associations between television watching and cognition six years later were compared while controlling for other factors such as demographics, depression, health behaviors, socio-economic, etc., suggesting more than 3.5 hours per day of television viewing is related to cognitive decline (McDermott, 2019). According to researcher Daisy Fancourt, there has been a dearth of studies dedicated to the effects of TV on the minds of the oldest viewers even though scientists have speculated a connection between too much screen time and dementia for decades. Older Americans, therefore, are encouraged to incorporate more activities like reading books, listening to music, and socializing with friends to balance potential ill effects of TV (McDermott, 2019).

Psychological Impact of Television

Fouts (1989) explicated a number of potential motivations for why the elderly are so attached to television as a medium. Those motivations included “information-seeking,” “entertainment,” “topics for conversation,” “to help schedule their daily activities,” “for substitute companionship,” “sharing the viewing experience,” correlating with one’s “self-concept,” and correlating with one’s “sensory decline” (Fouts, 1989, pp. 570-571). Fouts argued that the more motivations the elderly had for watching television, the more they would use it. While all of these motivations might not be unique to the elderly, there does seem to be a nexus of issues driving the elderly to the screen, as getting older means losing loved ones and not being able to get around easily.

The loneliness motivation is something that continues to be found in more recent research. Eggermont and Vandebosch (2001) studied 284 people 60 years and older. First, their consumption was nearly double the general population. “Parasocial interaction, loneliness relief, passing time, boredom avoidance, and activity substitution are obvious viewing motivations” (p. 10). The life circumstances of

the elderly, such as a lack of social connectivity, seemed to drive television use and a connection with the characters they saw on the screen.

Nguyen, Wittink, Murray, and Barg (2008) cited previous research potentially connecting television use with depression in the elderly. The researchers, however, set out to study what people 65 and older thought themselves about the relationship between television and depression. Elderly respondents said that TV use could cause them to realize they were depressed because they were over using it, that TV could be a coping mechanism for dealing with depression, or that TV could be a trigger for depression or could make depression worse.

What the elderly think about TV is also what drove research for Van Der Goot, Beentjes, and Van Selm (2012). In studying Dutch people 65 and up, the researchers found that television viewing had changed for respondents based on available free time, based on social and familial changes, and based on TV content itself. Some people watched more TV because retirement offered that ability, though others watched less because they did not need TV for relaxation from their job. Some watched more TV after a spouse's death. Some watched less TV to avoid painful memories of those who they have lost. Finally, some watched new TV genres because they no longer had a spouse to compromise with on choice or because they wanted to stay mentally sharp. Others found they had to turn off some genres as they had become more sensitive to the content. While it is true that people might turn to television as they age, such research shows this group is far from a monolith in terms of both motivation and behavior.

SOLUTIONS AND RECOMMENDATIONS

As the oldest Americans are both the most sedentary and least connected (Anderson & Perrin, 2017; de Rezende, Rey-López, Matsudo, & do Carmo Luiz, 2014), more outreach work must be done to ensure such people are not falling through the cracks both in terms of digital connectivity and overall health. Social networks do seem to have the capacity to be beneficial to the elderly, leaving those who use it feeling overall healthier, suffering from fewer chronic health issues, and experiencing less depression and loneliness (Frank, 2018).

The elderly can often find free programs that offer classes to train them in computers. Classes can also be found at senior citizen centers, libraries, and colleges (Frank, 2018). These courses offer real-world solutions for not just getting the elderly online, but for turning them onto the newest technologies and media trends.

Passively offering courses on computers might be enough to push the elderly to Google their medication, try out social media, or build a website (Frank, 2018), but it might not be enough to change literally decades of television habituation. Where are the classes for OTT services such as Netflix and Hulu? How many courses offer seniors a chance to go hands-on with streaming devices, such as a Roku Player or an Amazon Fire TV Stick? Classes do exist to teach seniors on how to use smartphones and tablets (Orlov, 2016), but such offerings are for older people who are already motivated to learn these new technologies. Who is evangelizing these technologies to the elderly? Who is showing seniors how much more convenient streaming can be than traditional television? How liberating watching the news on a tablet anywhere can be? How one can watch the game on TV and connect with like-minded sports fans with a smartphone to enjoy a second-screen experience (Poltrack, 2012)? While having classes on computers for the elderly is clearly a good thing, there also needs to be classes that align with how people actually spend their leisure time today. And waiting for students to show up is not the solution here. Again, outreach is the key.

FUTURE RESEARCH DIRECTIONS

Seniors lag behind younger Americans when it comes to overall technology adoption. However, seniors are adopting new digital technology (mobile, tablets, etc.) at an increasing rate. As consistent with younger audiences, adoption of new technology is sure to impact traditional television viewing as well as the way television content is consumed. According to the Pew Research Center (2014) more than 59% of seniors reported they go online (six percent increase from the previous year) with 47% having access to high-speed broadband connections. New technology adoption increases even more when considering a subgroup of seniors who have a higher social status, education or financial liquidity. As stated in the Pew Research Center (2014) study, “Younger, higher-income, and more highly educated seniors use the internet and broadband at rates approaching-or even exceeding-the general population.” This is consistent with Rogers’ (2003) diffusion of innovations perspective on early adopters as a subgroup of the senior population. As the diffusion curve moves, more adoption and changes in television consumption should be anticipated. Research opportunities are ripe to review how and at what rate older Americans adopt technology as well as how their television consumption, based on this adoption, has changed.

Additionally, television program content providers are moving access to broadband, on-demand, and DVR-based viewing platforms in homes adopting newer technology such as smart televisions. Approximately 32% of all televisions in U.S. households are now considered “smart,” allowing for streaming of content via applications from the internet, with 14% of U.S. adults watching daily. Combine this with nearly half of all U.S. homes having at least one stand-alone streaming device (Frankel, 2019) and it is clearly understood how content delivery is changing. Streaming is becoming mainstream, and thus understanding how the elderly are participating in this shift, or not, is of great importance.

Online content providers such as Hulu, Netflix and Amazon are partnering with traditional broadcast and cable networks to provide programming in new ways as well. Traditional networks are also creating interactive experiences in via web and mobile viewing platforms. Increased participation in social media from audiences, television content brands and seniors is sure to impact viewing habits. Also, as generations’ age, their familiarity with technology will change. Additionally, the impact of technology on television consumption is sure to change the traditional viewing model for seniors in the future. There is no doubt media delivery (aka binge watching) will continue to change consumption habits and there is currently no research examining how this behavior will impact the physical or emotional wellness of the elderly.

CONCLUSION

This entry communicates the television consumption habits of seniors currently differ from the general population. However, technology will continue to have an increased impact in viewing habits in the future. Television consumption in the senior population is a ripe area for research since people are living longer and availability of television via digital technology is becoming more mainstream. While there is significant information in terms of industry trend data there seems to be a general deficit in scholarly data examining the impact of television consumption as well as technology delivery on the senior generation.

KEY TERMS AND DEFINITIONS

Cord-Cutting: The act of canceling a subscription to cable or satellite to consume television content via online content providers such as Netflix, Hulu, or others.

Dementia: A general term for a decline in mental ability severe enough to interfere with daily life. Memory loss is an example. Alzheimer's is the most common type of dementia.

DVR Technology: Digital video recorder is an electronic device that is used to record and play back video content. Many cable and satellite services provide DVR technology as part of the consumer package.

Elderly: People over the age of 60 years old.

Online Content Providers: Text, video, and audio delivered via the internet.

OTT: Over the top television is any television content delivered via an internet connection. Examples of OTT providers are Netflix, Hulu, Amazon Video, etc.

Penetration: Percentage or share of an adopted technology.

Second-Screen Experience: The use of a screened device, such as a smartphone or tablet, while watching another screen, such as a TV or a computer, to enrich the viewing of a program.

Sedentary Behavior (SB): Behaving in a manner that is not physically active, such as sitting and watching television and not standing or moving one's body.

Streaming: The digitization of content delivered via internet. Often also referenced as streaming TV, online TV, or internet TV. Examples of this include Netflix, Hulu, Amazon Video, etc.

Television Consumption: Any time spent watching live or recorded television, viewing DVDs, and streaming shows on their TV sets, computers, and portable devices.

Time-Shifting: Recording a program to a storage medium to be consumed at a later date.

Social Media and Social Movements: Strengths, Challenges, and Implications for the Future

INTRODUCTION

Collective action to advance social change is part of cultural tradition in the United States. Throughout American history, many Americans have advocated for both structural and cultural changes through charismatic leadership and collective action. Regardless if the goal has been for women's right to vote, free lunches for all students, or access to clean water for all Americans, having the freedom to protest and assemble are important components for any democratic society (Carroll & Hackett, 2006). Additionally, the creation of social movements has an underlying goal to incorporate new actors in the political process (Garrett, 2007).

Because of the increasing importance of the link between social media and social movements, recent research attempts to bridge the gap between media studies and sociological research on social movements. For example, Gerbaudo (2012) explores the culture of social movements in his book "Tweets and the Streets: Social Media and Contemporary Activism" arguing that the media provides a channel through which social movements are organized and further developed. He also argues that social media allows individuals to develop connections to others who may have similar interests and causes. However, Morozov (2011) points out that social media facilitates "slacktivism", that is activism for "slackers." Morozov argues that individuals may perceive they are fighting injustice by joining a Facebook group or retweeting, but their actions may have little to no political or social impact.

Therefore, questions remain unanswered. Does social media help facilitate activism that leads to social change? What are the strengths and limitations of social media in creating and maintaining a social movement? We explore these questions and others in our article paying particular attention to the #Blackslivesmatter (BLM) social movement, which according to Lebron (2017) is a powerful force demanding social change in America. The hashtag #Blacklivesmatter was created in July 2013 in response to George Zimmerman's acquittal for the second-degree murder of an African American teenager, Trayvon Martin (Freelon, McIlwain, & Clark, 2016). The watershed moment for this social movement was the fatal police shooting of African American youth, Michael Brown who was shot by a white police officer in Ferguson, Missouri on August 9, 2014 (Anderson & Hitlin, 2016). The authors of this article focus on this social movement because both scholars and activists suggest that BLM is responsible for increasing social awareness regarding police brutality towards Black Americans (Garrett, 2007).

DOI: 10.4018/978-1-7998-3479-3.ch075

BACKGROUND

On February 1, 1960, four freshmen students from North Carolina Agricultural and Technical College went into a store in Greensboro, NC and sat down at a lunch counter that had been deemed for whites only. The four students were not served but remained seated at the whites-only counter until the store closed. Although the student sit-ins appeared to be an unplanned event, there was a great amount of planning that took place before the sit-ins occurred. All four of the students were members of an NAACP Youth Council and had been in contact with other activists who had participated in sit-ins in the late 1950s (Polletta, 2006). The actions of the four students—Ezell Blair Jr., David Richmond, Franklin McCain, and Joseph McNeil—suggested a spontaneous, impulsive form of resistance, rather than a planned social movement. Consequently, Polletta (2006) argued that the spontaneous nature of the sit-ins suggested a powerful moment when a group of individuals suddenly become a *collective force* undertaking social injustice. Yet, these events were part of a much larger, powerful, and historically significant form of collection action in the United States: The Civil Rights Movement.

What is a Social Movement?

Social movements are the collective action of individuals who come together for the purpose of achieving a goal that challenges society's cultural or structural beliefs. Goodwill and Jasper (2009) describe social movements as “being conscious, concerted, and sustained efforts by ordinary people to change some aspect of their society by using extra-institutional means” (p. 5). Formal organizations are created because of social movement while others rely on the informal networks. Therefore, using a rigorous definition for social movements may exclude the work of less mainstream causes.

Scholars identify four stages of social movements, including emergence, coalescence, bureaucratization, and decline (Jones-Eversley et al., 2017). Jones-Eversley and colleagues (2017) argued that these four stages can be applied to both the Civil Rights Movement and BLM. The first stage, *emergence* refers to when the social movement has little organization for how to redress their dislike for a certain policy or social condition. During this stage, people are acting as individual agents not as a collective unit. For example, a person may send a letter or email a representative to voice his or her opinion or they may post their view on a popular social media site. Once in the second stage, *coalescence*, like-minded individuals gather together to focus their message. The movement is more organized to state grievances as a group towards a person, policy, or social standard. In the online context, this stage may have a hashtag (i.e., #metoo, #occuywallstreet) that gains the public's attention. The next stage, *bureaucratization*—the foundation of the social movement—is organized with political power. Now the social movement has moved away from demonstrations of awareness to having a formal organization working towards their collective goals. The final stage is *decline*. Decline occurs due to success, failure, or a disinterest in the movement. Applying these stages to one of the most significant social movements in American history, the Civil Rights Movement progressed through these stages from Rosa Parks refusal to give up her seat, the boycott of the Montgomery bus station, NAACP legal involvement, and finally the case Browder v. Gayle to end racial segregation on Alabama buses (Browder v Gayle).

What is Social Media?

Social media is an umbrella term used to explain the networking of communication and collaboration online (Friedland, 2013). The general formats rely on individuals connecting and networking with others

in multiple forms and functions. Several networking sites have platforms that serve different purposes of sharing information. Worldwide, the social media website with the most users is Facebook. Globally, the United States has the second-greatest number of Facebook users (190 million), following behind India (270 million) (Statista, 2019). Facebook is best known for personal interactions to stay connected with friends and family. In the United States, as of July 2019, there were over 48 million Twitter users (Statista, 2019). Twitter users reach a large audience of “followers” for fast, short information. Instagram relies on interactions between users and the follower sharing pictures, videos, and visual media. LinkedIn provides users the ability to maintain formal networks for employment and professional relationship. In addition to this being informal networks online, there are interactions with state officials, celebrities, businesses, and powerful individuals.

Using social media to communicate is breaking down barriers of reaching potential followers and influential individuals. Social media provides an open access to dialogue that is decentralized (Freberg, 2013). It does not rely on one-way dissemination of content and the cost to create content bare little or any expense. Unlike traditional platforms of communication (e.g., newspapers), social media has little delay, which allows it to break barriers of time and location. For many social media users, checking social media websites is part of their daily routine, as Pew Research (2018) estimates that three-quarters of Facebook users and six to ten Instagram users visit these sites at least once a day.

There are various types and purposes of social media. As shown in Table 1, social networking websites, such as Myspace (founded in 2003), Facebook (founded in 2004), and Twitter (founded in 2006) are typically used as a space for social interaction with family, friends, and other followers. A “follower” on social media refers to someone who subscribes to receive a person’s updates (Beal, 2019). Social networking websites can be used to both maintain and develop new social connections. Social review websites, such as Yelp and TripAdvisor are utilized to share reviews of businesses with potential customers. On image sharing websites, such as Instagram and Pinterest (both founded in 2010), users can share images with their friends and followers. Video hosting websites, including Vimeo and YouTube

Table 1. Summary of Types and Purpose of Various Social Media Platforms (2000-Present)

Website Type	Purpose	Example & Founding Year
Social Networking	Users can interact with friends and followers and develop new social connections.	Myspace (2003) Facebook (2004) Twitter (2006)
Social Review	Customers leave reviews for other potential customers.	TripAdvisor (2000) Yelp (2004)
Image Sharing	Users can share visual content with other users and followers.	Instagram (2010) Pinterest (2010) Snapchat (2011) VSCO (2011)
Video Hosting	Users can create and share videos for streaming by other users.	Vimeo (2004) YouTube (2005)
Community Blog	Users can express their thoughts and ideas in a blog format.	Tumblr (2007) Medium (2012)
Discussion	Specifically designed to facilitate discussions among users.	Reddit (2005) Quora (2009)
Sharing Economy Networks	Allows users to share resources with one another.	Airbnb (2008) Rover (2011)
Source: https://biteable.com/blog/tips/the-7-different-types-of-social-media/		

allow users to both create and share videos for others to stream online. Community blogs allow users to express their feelings on various topics, while discussion websites, such as Reddit and Quora help facilitate conversations and debates. Finally, sharing economy networks provide peer-to-peer selling and sharing of resources based on an individual's specific needs (e.g., a dog walker, overnight accommodations for a trip, etc.) It is important to note that there is connectivity between many of the social media platforms. For example, a user can post an image on Instagram and then share that post with friends and followers on Facebook.

How can Social Media be used to Facilitate Social Movements?

Social media has become influential in promoting and organizing social movements because it combines the use of digital communication and engaging dialogues to solve social problems. With the use of social networking sites, anyone can be aware of a global or local event within seconds. As videos of current events are posted online, testimonies often flood news feeds and there is a personal touch added to each event. Once there is awareness of an issue, social media facilitates a place to organize the cause and show support to others. Gerbaudo (2012) argues that the media provides a channel through which social movements are organized and further developed. Access to social media is a crucial tool for large groups to organize. The information is disbursed in a timely manner to a large audience. Developments are made by contributing ideas to the future of the movement. Being online allows everyone's voices to be heard. In place of traditional media's designated spokespersons, multiple voices from all walks of life produce user-generated content in social media (Freberg, 2013).

In the digital era, there is a heightened awareness about social issues. Accountability for being aware of the discourse that occurs in our communities is important. Social media allows individuals to participate in activism and demonstrate support to causes an individual may not be able to reach physically. The use of hashtags makes the process of claim-making easier because it gains momentum as it is used at a large rate. Previously mentioned social media sites, Facebook, Twitter, and Instagram have trending pages for top mentioned topics and hashtags. For example, the #IceBucketChallenge brought awareness to the ALS (Amyotrophic Lateral Sclerosis, also known as Lou Gehrig's disease) Association. What started as a fun way to challenge others to donate money raised \$115 million in the summer of 2014 (Rogers, 2016). In 2018 the #metoo hashtag demonstrated support for survivors of sexual harassment and assault, which brought increased awareness to the pervasiveness of these crimes (Johnson & Hawbaker, 2018).

#BlackLivesMatter

The BLM hashtag serves as the *coalescence* stage of this social movement; it brought awareness to social injustice while bringing together a community against police brutality. The BLM movement was started by three Black women; Alicia Garza, Patrisse Cullors, and Opal Tometi (Garza, 2014). These women came together to oppose police violence and injustice against Blacks, later to expand their cause. The hashtag #Blacklivesmatter was created in July 2013 in response to George Zimmerman's acquittal for the second-degree murder of an African American teenager, Trayvon Martin (Freelon, McIlwain, & Clark, 2016). After July 2013 through May 1, 2018, the hashtag has been used nearly 30 million times on Twitter (Anderson, Toor, Rainie, & Smith, 2018). After gaining a core group of participants, the founders published their list of demands that would be the guiding principles of the BLM association. According to D.C. Area Educators for Social Justice: A Project for Teaching Change (2018), included in the guiding principles are restorative justice, diversity, queer-affirming, globalism, unapologetically

Black, collective value, empathy, loving engagement, transgender affirming, Black villages, Black women, Black families, and intergenerational.

After June 2014, the hashtag use was declining on the Twitter platform. Months later after the death of Eric Garner, there was an uptick followed by silences. Twitter activity around this time was still relatively small in scale compared to the attention to come after the death of Mike Brown (Freelon, McIlwain, & Clark, 2016). The death of Mike Brown in Ferguson, Missouri was the catalyst that made BLM the well-known political activist group today. After June 2014, the hashtag use was declining on Twitter (Anderson, Toor, Rainie, and Smith 2018). Over the past five years BLM has been used on a continuous pace with significant events. According to findings from the Pew Research Center, the BLM hashtag was mentioned an average of nearly 500,000 tweets daily between July 7th and 17th (Anderson et al., 2018). This social movement has surpassed the hashtag, and according to Lebron (2017), BLM is a powerful force demanding social change in America. In the case of BLM, social media was a symbolic megaphone, allowing voices of neglect, mistreatment, and injustice to share their stories for the world to hear.

THEORETICAL CONSIDERATIONS

The application of sociological theory can provide a better understanding of what social media means for modern social change. In order to explain collective behavior, such as social movements, some scholars argue that it is imperative to pay attention to resources, and the *resource mobilization perspective* suggests that the aggregation of resources, that is, money and labor are critical for an understanding of social movement activity (McCarthy & Zald, 1997). Resource mobilization theory emphasizes resources, organization, and political opportunities as a means for social change (Jenkins, 1983). Resource mobilization theorists suggest that social movements are extensions of institutionalized actions, focusing on institutional change and previously unorganized groups that form together against institutional elites (Jenkins, 1983).

The social psychological version of resource mobilization theory suggests that at the individual-level, a person weighs the costs and benefits of participating in a social movement and (1) knows the opportunities to participate, (2) determines if he/she is capable of engaging in the opportunity, and (3) decides if he/she is willing to participant (Klandermans, 1984). More recently, Polletta and Jasper (2001) focus on collective identities and why they matter to social movements. They argue that the term *collective identity* describes both imagined and concrete communities that are fluid and relational. Collective identities form through bystanders, allies, opponents, and news media (Polletta & Jasper, 2001). They also argue that collective identities matter to social movements because they promote new identities as a mechanism to achieve power and transform selves (Polletta & Jasper, 2001).

Drawing from resource mobilization theory, it is important to consider that social media acting as an avenue for social change is limited by technological capital. Individuals' access to the Internet and social media is based on access to and the availability of valued resources, which depends on the demographic characteristics and resources of particular groups (Carlson & Isaacs, 2018). That is, not everyone in society has equal access to different forms of technology, including the Internet. This means that social media may be more influential in mobilizing certain sectors of the population, including those with the greatest resources. While researchers suggest that the number of people *not* engaged with social media are dwindling, there are still those without it, which imposes a limit for the use of social media as a platform for facilitating social change (Anderson & Hitlin, 2016). Because access to technology is

a privilege not everyone has, online protests may be excluding some of the most marginalized groups in society. Underrepresented groups in America often lack a voice in matters of social, political, and economic injustice, and they are the least likely to have access to technology. This in turn, restricts their participation in social media and online social movements.

To forge a multi-dimensional understanding of the struggles of some of the most marginalized groups in society, the theoretical framework, intersectionality focuses on multiple social identities of individuals and groups and society, including race, social class, gender, sexuality, disability, nationality, among others. Drawing from Crenshaw's (1989) *intersectionality*, Collins (2000) argued that an intersectional approach is particularly useful in order to gain a more thorough understanding regarding how forms of intersecting categories of oppression influence individuals' lives. An intersectional approach underscores that discrimination and inequality are experienced differently among marginalized groups, which is relevant to the manner in which people individually and collectively organize to fight against injustice. Individuals do not experience injustice as one category of their social identity. Instead, the ways in which gender, race, sexuality and other social identities are entangled, shapes individuals' experiences with various forms of injustice in the United States (Collins 2000). Chun, Lipsitz, and Shin (2013) argued that intersectionality infuses collective behaviors, especially those organized by women of color. As we see with BLM, the original social movement was started by three individuals who identified in at least two marginalized groups: Black women. Therefore, intersectionality is useful in demonstrating that discrimination and inequality are experienced differently not only among marginalized groups, but also among groups of individuals experiencing multiple forms of oppression (Choo & Ferree, 2010; Collins, 2000; Miller, 2006; Moore, 2011).

FUTURE RESEARCH

Social media is still a relatively new phenomenon and because of this, prior research is limited. Longitudinal research is extremely beneficial in studying social changes long-term because of the opportunity to see changes in habits and behaviors over time. Within the realm of social media, longitudinal research is lacking because of its novelty, meaning there lacks a significant amount of information for data comparison. Previously conducted studies have been restricted to individual social media platforms such as Twitter or Facebook (Tow et al., 2010; Khan & Jarvenpaa, 2010). Considering recent and ongoing technological advances, integration of social media platforms now allows for easier and more complete research across online sites. Additionally, age is a limiting factor in prior research. At its conception, social media was associated and marketing to younger users, and scholars have largely failed to consider the older population use of social media sites. Consequently, there are gaps in the research regarding the population as a whole and the link between social media and social change (Vishwanath, 2015).

In addition to considering the use of longitudinal data collection and analysis, drawing from Harlow's (2011) research on social media and social movements, the authors of this article recommend that future research should consider how social movements may begin online and then move offline or vice versa. Internet users may become interested in a topic from a post or hashtag on a social media site, which may in turn, may contribute to offline protests and further collective action (Harlow, 2011). Or offline grassroots organizations may gain social media attention, which gives their collective action further momentum, facilitating it into further stages of a social movement. Future research should consider these unique paths as organizations fight for justice, including when social media is a driving force behind a

social movement or when social media advances an already present social movement further igniting pro-justice collective action.

CONCLUSION

The ability of individuals to come together to advocate for social change is an important part of America's history and tradition. In fact, over the past several decades, several social movements have transformed the culture of American society, including the Labor Movement, the Women's Movement, the Civil Rights Movement, and the LGBT Movement. More recently, Occupy Wall Street brought awareness to income inequality and inequity in American society, and today, we are seeing the power of the Internet as the BLM hashtag has become a key symbol of a social movement against police brutality, violence, and racism against African Americans. As social media websites and platforms continue to develop and change, we may see a renewal of prior social movements, and the growth of social awareness about new social causes. It is important that all people have a voice in advocating for change; consequently, the Internet allows for each person to have a voice. Through Facebook, Twitter, Instagram and other social media websites, the ability to connect and network with others is what helps propel that one voice into a larger group of voices who together, have the power to fight for change and justice.

KEY TERMS AND DEFINITIONS

8

#BlackLivesMatter (BLM): A hashtag, created in 2013 that campaigns against police brutality, other forms of violence, and systemic racism against Black people.

Follower: A term used to describe an individual who subscribes to receive a social media user's updates on social media websites, including Facebook, Instagram, and Twitter.

Intersectionality: With an emphasis on the experiences of women of color, intersectionality is a theoretical perspective, developed by Kimberlé Crenshaw in 1989 that focuses on marginalized individuals' intersecting social identities.

Resource Mobilization Theory: A theoretical perspective that addresses the resources (time and money), organization, and political opportunities needed for social change.

Social Media: Online platforms that are used for social networking and sharing information and ideas.

Social Movement: Individuals or groups of individuals that come together to facilitate social change.

Digital Social Networks From a Social Capital Perspective

INTRODUCTION

Digital Social Networking (DSN) sites such as Facebook, Twitter, LinkedIn, WhatsApp, Instagram, Pinterest among many others have garnered millions of users worldwide. This instance of information and communication technology has brought about changes in the way people communicate and interact affecting human lifestyle across the world. According to many, the phenomenon has permeated geographical and cultural boundaries, disregarded age and gender barriers, diffused social and economic strata, and transgressed linguistic and ethnic boundaries. Such widespread and intense impact of technology on human life is unprecedented in human history. The unique opportunities offered by digitization of social networking, the novel capabilities of information dissemination and foraging on DSN sites, along with widespread adoption have generated academic interest in the theoretical interpretation of antecedents and consequences of DSN adoption. In this chapter, the authors offer a social capital perspective of DSN adoption.

Social capital is a manifestation of the underlying social network. It has a symbiotic relationship with social network. Social capital is determined by network mechanism, and reciprocity, both at a general and individual level. The concept of social capital applies the economic principle of rational action and economic systems to social systems maintaining its social structure. Like human capital, social capital is less tangible than physical capital but displays the potential to facilitate economic output by boosting productivity and trust. Human capital is an individual attribute, whereas social capital is an attribute of human relationships. Social capital allows conversion to other forms of capital such as human capital and intellectual capital. It distinguishes itself from financial and human capital as it is owned wholly or in parts by individuals and acts as a catalyst in mobilizing financial and human capital.

BACKGROUND

DSN is a culmination of the rapid evolution of information technology, aided by revolutionary advancements in telecom and computing technologies. The first decade of the twenty-first century witnessed the emergence of DSN sites such as Friendster, MySpace, LinkedIn, Flickr, Facebook, Twitter, WhatsApp, Instagram and many others, refer Figure 1. Millennials have adopted DSN as part of their daily

DOI: 10.4018/978-1-7998-3479-3.ch076

Figure 1. Users on popular DSN sites (adapted from Statista, 2018)

existence. It has empowered users to create and share content, a big difference from general users being mere consumers of content. The rapid proliferation and wide adoption of DSN has had a profound effect on social, economic, political, organizational and emotional aspects of human life (Kane et al., 2014).

DSN sites are defined as “web based services that enable users to (1) construct a public or semi-public profile within a bounded system, (2) articulate a list of other users with whom they share a connection, and (3) view and traverse their list of connections and those made by others within the system” (boyd & Ellison, 2007, p. 2). DSN allows users to create and exchange user-generated content, which empowers general users to publicly voice their opinions and views and find an audience for their creativity. DSN sites constitute websites facilitating networking or relationship building between people. Networking typically refers to forming a relationship with strangers. DSN allows people to network - to connect with strangers and expand their social horizon. It allows users to articulate their profile and make their profile and connections visible in the network (boyd & Ellison, 2007). The profile search feature on SNS aids users find people with similar interests and form new connections. It allows users maintain the relationship with their existing networks. In consequence, it aids users to maintain a larger network on DSN compared to offline social networks.

DSN affordances of expanded social reach aided by communication richness grants a paradigm shift towards enhanced social networking. This endows DSN users an opportunity to enhance their social capital on DSN. Uslaner (2000) proposed that spending more time on the internet encumbers face to face interaction which is detrimental to social relationships. DSN has belied this dystopian view - it promotes social interaction. It facilitates the meeting of like-minded people forming communities of common interest and shared goals. This improved interaction promotes social capital (Hofer & Aubert, 2013). Academic studies found that DSN show positive association with community interaction, involvement, and social capital (Ellison et al., 2007; Ellison et al., 2011; Hampton & Wellman, 2003).

SOCIAL NETWORKING

Social network theory, proposed by Jacob (1934), interprets social relations and actions for a contextual, relational and systemic understanding of human behavior. In social network theory, social relations are

represented by a structure of nodes and edges, where the nodes represent people or groups, and the edges represent interaction, collaboration and influence between the nodes. A number of nodes and edges together represent the social network. Networks constitute direct and indirect ties between nodes. Direct ties between nodes form relationship dyads and triads. Structural holes indicate absence of ties for triadic closure (Bapna et al., 2017). Network analysis shows that nodes associated with large number of structural holes enjoy more power in the network (Burt, 1992a). Directed network ties (example: manager to a subordinate) comprise of unequally connected nodes that support unidirectional or unbalanced network flow. Undirected network ties (example: peers) constitute nodes with equal connection on either side where network flows are bidirectional. Different types of ties represent different types of relations (example: partner, competitor).

In the social network, the tie-strength measures the strength of the relationship (Granovetter, 1973). Weak ties constitute loose connections between people that serve as information conduit (Putnam, 2000). Weak ties in a network are inclusive in nature and effective in broadening one's social horizons, connecting with people from different life situations and opening up opportunities for more information and resources (Williams, 2006). Strong ties are seen between close friends and family members. The term ego-network (Koka & Prescott, 2001) refers to a network represented by ties of a focal node, where the focal node is called an ego, and the other nodes are known as alters. In a larger context, academicians refer to the network structure as a network of networks, where each individual network displays stronger tie strength between its nodes and is distinguished by some intrinsic characteristics; and yet the smaller networks are not discrete, there are interlinks and overlaps.

Academic researchers have characterized network structures, refer Figure 2, by centrality (the degree to which relations are guided by network hierarchy), closeness (the network distance), betweenness (node

Figure 2. Social network

lies between other nodes in the network), multiplexity (multiple network paths between nodes), holes (nodes is connected to two others which are not mutually connected) and cliques (clusters of networks connected to one another) attributes (Liben-Nowell & Kleinberg, 2007). The attributes of the nodes and the attributes of the ties produce a distinct effect on the influence of the tie. Attribute-based differentiation generates cliques or clusters within the network, such as location-based clique or skill based clique. Social network theorists have posited that the network influences are the effect of ties and network position, decimating the need to study attributes of the node. This view theorizes that the attributes of the nodes manifest in their position, as similar nodes occupy similar positions in the network (Wellman et al., 1996). Rowley's (1997) social network model studied the network density and organization's centrality in the network to examine structural influences. In network terms, density refers to the relative number of ties linking network nodes. Centrality of network nodes determines the influence of the node to group proficiency and behavior (Kane & Borgatti, 2011).

Social network researchers study the formation, expansion and changes in social structures, impact of characteristics of the network, likelihood of ties between members of the network and formation of social capital (Pool & Kochen, 1979). Structure of the social networks and allocation and flow of resources within the network constitute predicting factors of social behavior in the network (Wellman et al., 1996).

DIGITAL SOCIAL NETWORK

DSN has gained wide popularity across the globe. It has become the de facto platform for users from varied backgrounds to connect with friends; share and find content. DSN allows users to create personal profiles, search profiles in the network, form network, create communities, generate content and share information and views which are easily dispersed and discovered in the digital network. The backbone of digital social networking sites consist of profiles having descriptors like age, location, interests, etc. and an articulated list of friends or connections. Information shared on these sites circulates across the globe instantly and generates comments and unique responses such as "like" and "share" (Lipsman et al., 2012). Users search SNS profiles to locate offline friends and form new connections, often with like-minded people evincing similar interests and views (Ellison et al., 2007). Table 1 lists typical features of DSN.

Prevalent DNS sites present a fairly consistent set of key network characteristics as well as technological features. Some minor variations in implementation of social networking characteristics along with variance in focus result in attracting different types of users and user behaviors (Lee & Suh, 2013). The sites vary in the extent of profile visibility, and access to connections and profile content. For example, Facebook requires elaboration of user's personal information for profile creation; Twitter preserves users' anonymity, thus creating a structural difference between the two platforms. User anonymity allows

Table 1. Typical features of digital social networking platforms

Feature	Description
Digital profile	Profiles having descriptors like age, location, interests and an articulated list of friends or connections.
Search	Search for profiles and contents and traverse the network.
Privacy	Allow or limit access to profile and digital content.
Content generation	Generate textual and multimedia content and share information and views.
Digital responses	Responses include text, "like", "share", emoticons.

focus on the communication content as opposed to the perpetrator of the information. Facebook supports bidirectional connections where the connection represents friendship that manifests equally on both the nodes. Twitter supports directed connections, with a follower on one end of the connection and a followed on the other end (Hofer & Aubert, 2013). Network closeness showed positive association between self-disclosure and communication frequency on Facebook (Bapna et al., 2017). These implementation variations lead to variation in performance of DSN sites and the consequences of DSN use.

DIGITAL VERSUS TRADITIONAL SOCIAL NETWORKING

DSN allows users to voice their opinions, views and share content and percolates the user generated content to a large audience through the network (Kaplan & Haenlein, 2010). Digital personal profiles are articulated and discoverable in the network. Profile and content search feature of online SNS platforms allow users to locate profiles with specific attributes. DSN is dynamic, growing and change rapidly over time, with the addition of nodes and new interchanges along the edges (Liben-Nowell & Kleinberg, 2007). It facilitates relatively more uninhibited and creative communication compared to in-person offline communication. Online social networking platforms allow systematic and quick flow of information and social support, which differ from the content flow in traditional social networks (Kane et al., 2014). The platform offers novel affordances, such as content multiplicity and unique responses such as “like”, which are not supported in traditional offline communications (Lipsman et al., 2012). The communication, interaction and collaboration capabilities of online SNS outstrip time and space limitations. This small world has become even smaller with DSN (Fu, Liu, & Wang, 2008). Offline social networks are mired with network cliques that displayed intense relationships in the inner circle (Dunbar & Spoor, 1995). DSN allows formation of new ties to expand the network boundary and form inter-group ties garnering more openness and inclusiveness in the network. Social stratification of like individuals increases the probability of two individuals having a minimum referral chain with a common friend, but the awareness of this minimum chain is uncertain in offline scenario (Pool & Kochen, 1979). Identifying the right path in the chain is difficult in offline social networks. Online referral webs have eased identification of minimum referral chains (Kautz et al., 1997).

DSN sites have increased the availability of data on social networks, which improved opportunities to study the basic properties and recurring structural features of social networks (Liben-Nowell & Kleinberg, 2007). It offers an easy and economical means to form and maintain a large number of ties, thus allowing users nurture a larger number of existing offline ties as well as new ties formed online (Ellison et al., 2007) to expand their network. Online communities have allowed individuals to shift from location-based networks or offline social groups to interest-based networks (Wellman, et al., 1996). Economic access to DSN has promoted subscription to interest-based virtual communities (Williams, 2006). On DSN platforms, ties are more observable, searchable and quantifiable compared to traditional social networks. This has improved opportunities for social interaction and consequent social capital generation.

SOCIAL CAPITAL

The term social capital (refer Table 2) appeared in social science literature dating back to the early twentieth century (Hofer & Aubert, 2013). The concept resurfaced in the 1960s (Putnam, 2000). The concept of social capital applies the economics principle of rational action (Coleman, 1988). Like human

Table 2. Social capital definitions

Author	Definition
Hanifan (1916)	"... good-will, fellowship, mutual sympathy and social intercourse among a group of individuals and families who make up a social unit" (p. 130)
Coleman (1988)	"Social capital is defined by its function. It is not a single entity but a variety of different entities, with two elements in common: they all consist of some aspect of social structure, and they facilitate certain actions of actors – whether persons or corporate actors - within the structure" (p. 302)
Burt (1992b)	"...resources available to any one person in a population are contingent on the resources available to individuals socially proximate to the person." (p. 60)
Adler and Kwon (2002)	"Social capital-understood roughly as the good-will that is engendered by the fabric of social relations and that can be mobilized to facilitate action..." (p. 17)

capital (Becker, 1962), social capital is less tangible than physical capital. It is an attribute of human relationships (Woolcock, 1998). Social capital acts as a catalyst in mobilizing resources and support to diffuse financial and human capital (Burt, 1992a). It yields individual and organizational performance variations by driving coordination, creativity, leadership, learning, teamwork, trust, career success, reduced turnover rate (Adler & Kwon, 2002).

Social capital is typically measured by tie strength (Helliwell & Putnam, 2004). Weak ties constitute loose connections between people. These ties serve as information conduit (Putnam, 2000). Putnam (2000) coined the terms "bridging" and "bonding" social capital (Williams, 2006). Weak ties in a network lead to bridging social capital, which is inclusive in nature and effective in broadening one's social horizons, connecting with people from different life situations and opening up opportunities for more information and resources (Williams, 2006). Strong ties, as seen between close friends and family members, lead to bonding social capital (Williams, 2006).

Past researchers studied social capital formation in terms of psychological imports such as self-efficacy, well-being, emotional support; social imports such as solidarity, trust and trustworthiness, civic and political impacts; and business gain (Burt, 1992b; Ellison et al., 2007; Granovetter, 1973). Increase in social capital leads to increase in commitment to the community, thus yielding benefits. Individuals leverage social capital to draw on resources from other members of the network. Declining social capital reduce trust among community members. Structural dimension of social network deals with social capital generated by virtue of the network, network structure, ties, tie strength, positions. Relational dimension deals with relationship attributes such as trust and goodwill. Cognitive dimension involves shared goals and norms. The cohesive strength of a community and collective efficacy determine social capital. Gaining access to resources in the social network is the primary function of social capital theory. The structural, relational and cognitive dimensions collectively influence mobilization of resources in the social network.

ROLE OF DIGITAL SOCIAL NETWORKING IN SOCIAL CAPITAL FORMATION

Researchers have often debated whether internet use leads to increase or decrease in social capital. When people spend more time on the internet, it results in less time and intent to meet people face to face. Consequently, stronger engagement with online platforms leads to a poor offline interpersonal relationship. On the other hand, enhanced interaction and larger number of connections supported by digital social networking is expected to facilitate formation of social capital. DSN allows users to maintain

touch with past ties leading to maintained social capital (Ellison et al., 2007). Frequent interactions in the network on diverse topics of common interests help users strengthen their social relationship ties, which induce relatively weaker ties to beget more bonding form of social capital. Information disclosure on DSN enables extending the network of weak ties, which in turn mobilizes resources and information (Ellison, Steinfield, & Lampe, 2011). Since DSN sites provision maintenance of both strong and weak ties, it serves as a platform for maintaining both bonding and bridging social capital. On the flipside, DSN allows connection across social, geographical and cultural boundaries, introducing complex virtual network relationships that could occasionally turn out to be dangerous and harmful.

SNS users maintain a connection with offline friends and form new connections online to form weak ties (Ellison et al., 2007). Bridging social capital emanates from weak ties or loose connections between people, which serves as an information conduit (Putnam, 2000). Ellison et al. (2007) study found a strong association between Facebook use and all types of social capital, where the association between Facebook use and bridging social capital was the strongest. Hofer and Aubert (2013) showed a differential effect of the directed network on social capital formation in their study of social capital generation on Twitter. Interestingly, their study showed that the number of followers was associated with bonding social capital and number of followees was associated with bridging social capital (Williams, 2006). Morris et al. (2010) found trusted information exchanges to be a motivation for information seeking on DSN. Wider and more frequent interactions on DSN serve to strengthen ties with network connections. The stronger network ties result in higher reciprocation and solidarity, emanating emotional support, and social and tangible benefits, which were determinants of bonding social capital. Ellison et al. (2011) found DSN use to exhibit significant association with bonding social capital.

IMPLICATIONS OF SOCIAL CAPITAL

Increase in social capital leads to increase in commitment to the community, thus yielding benefits. For example, social capital yields individual and organizational performance variations by driving coordination, creativity, leadership, learning, teamwork, trust, etc. Social capital facilitates psychological imports such as self-efficacy, well-being, and emotional support. The cognitive dimension of social capital capacitates collective goals to influence individual and group behavior, which improves group performance. It mobilizes workforce to adhere to quality processes, value-add and achieve continuous improvement.

Social capital is a core concept in business. Organizations gain competitiveness and generate returns from investments in social capital (Burt, 1992b), similar to investments in financial and human capital. Bridging social capital is effective in case of job searching, information diffusion, product quality, knowledge management and firm competitiveness (Borgatti & Foster, 2003; Granovetter, 1973; Putnam, 2000). Bonding social capital provides more substantive support that is useful in organization transformation (Williams, 2006). In large firms, sharing visions and values and understanding of common goals are necessary to develop the firm's social capital, useful in forming strategic alliances and buyer-supplier networks (Koka & Prescott, 2001). Social capital eases knowledge capture and its flow in large multinational corporations working with a global network of suppliers and other stakeholders. Information and resource access in the network through social capital is useful in career success of professionals (Seibert, Kraimer, & Liden, 2001).

Social capital in the organization's employee network generates job satisfaction, which fosters voluntary actions, value and innovation and promotes entrepreneurship (Koka & Prescott, 2001). In an external organizational network, social capital with strategic industry leaders, regulators and other people hav-

ing the power to influence organization performance provides a competitive advantage. Social capital in competitor network offers opportunities for beneficial collaborations. In short, use of social capital endows an organization the ability to maintain a strategic competitive advantage (Tsai, 2000).

Independent empirical research conducted by the authors of this chapter reinforced generation of social capital formed on DSN (Dhar, 2018). Principal component analysis on social capital items in the research instrument yielded three factors, where the bridging social capital sustained as a single factor, but the bonding social capital yielded two independent factors, namely, resource access and social support. This research showed positive association between DSN use and generation of all social capital factors. The study indicated perceived business benefits on strategic and operational dimensions from DSN use partially mediated by social capital formed on DSN. Thus, from a utilitarian perspective, social capital constitutes a critical component in determining consequences of DSN use.

FUTURE RESEARCH DIRECTIONS

Social capital is increasingly gaining importance in academic literature for its economic imports. DSN such as Facebook and Twitter allows unique social networking capabilities in terms of network structure and information flow in the network. This introduces new dimensions to social capital generated on DSN. Social capital influences a multitude of social aspects such as behavior, education, health and economic development (Adler & Kwon, 2002). It affects psychological aspects such as human attachment and reciprocity (Wasko & Faraj, 2005). It also affects economic aspects such as career success, performance and strategic alliances at individual and organization level (Seibert et al., 2001; Tsai, 2000). In consequence, differentiated social capital formation on DSN affects social, psychological and economic aspects of human life. There exists gap in academic research on understanding imports of DSN (Kane et al., 2014). The social capital perspective of DSN use portrays diverse potential consequences of DSN that call for research (refer Figure 3).

Figure 3. Future Research Agenda

Future researchers need to study the network and technological determinants of DSN that influence social capital formation. For example, novel technology attributes such as “like” manifests unique emotional consequences (Lipsman et al., 2012). Such emotions influence social interactions and relationships leading to differences in social bonding and intensity of social capital. Secondly, researchers need to determine social capital constructs emanating from DSN use. In a study conducted by Ellison et al. (2007) on association between DSN intensity and social capital, bonding capital items yielded two unique factors on, while the bridging social capital sustained as a single factor. This indicates the possibility of DSN use yielding new dimensions of social capital. Thirdly, researchers need to investigate the specific consequences of DSN use and the mediation role of social capital in the relationship. For example, DSN allows traversing network connections to connect with profiles having common interests, leading to bridging social capital. This is useful in knowledge sharing in distributed organizations (Ellison et al., 2015). Researchers need to explore similar consequences in organizational business functions, education, healthcare, old age care and other economic imports.

CONCLUSION

DSN is perhaps one of the greatest social upheavals of the twenty-first century. DSN adoption and influence have surpassed all past technology implementations. There exists a debate on the social and economic utility of the phenomenon versus harmful effects of DSN. There also exists a dilemma and lack of strategy in organizational use of DSN for business functions. There is a need for theoretical research to understand the underpinnings of DSN adoption and use followed by empirical investigation to explore the nuances of the theories. The social capital perspective of DSN discussed in this chapter offers a methodical approach to study DSN use.

KEY TERMS AND DEFINITIONS

Digital Social Network: Digital platforms that facilitate social networking, where individuals or groups (nodes) can articulate their profile and connections discoverable in the network and digitally interact with other nodes in the network.

Social Capital: Denotes goodwill, fellowship, help and sympathy among connections in a social network that yields benefits such as support, solidarity, and access to resource.

Social Network: Social relations studied as a network, where individuals or groups are represented as nodes and their relationship and interactions are represented by edges.

INTRODUCTION

Nowadays documents (e.g., books, articles, papers, etc.) are created electronically and they are printed electronically. Modern printers are programmable and so documents are uploaded to them as *programs* in some *page description language* (like PostScript, PDF, and PCL). Currently, PDF is the de facto industrial standard for printable documents so all documents are finally converted to PDF.

Definition A digital document is one that is created exclusively with digital means (e.g., computer programs), can be read with digital means (e.g., electronic book readers), and can be transferred to paper by purely digital means (e.g., fonts are digital and the printing machine transfers the digital document to paper).

Documents are created using either sophisticated GUIs or using an “advanced” text editor. Programs like MS Word and LibreOffice Writer are sophisticated GUIs that are used to create digital documents. On the other hand, one can create the same documents “manually” by using a simple text editor and/or some CLI tools. For example, it is entirely possible to create a document in the Open Document Format for Office Applications (ODF) with such tools and of course most people create their LaTeX documents using simple or advanced text editors like NotePad++.

The various file formats that are used to electronically encode documents based on the idea of *markup*. To understand what markup is consider a book that submitted for publication. Typically, a copy editor will annotate the text with various types of instructions. This is markup. In case, the markup is entered electronically, then, clearly, it is called *electronic* markup. *Specific* markup is a form of markup that tells the formatted to do each point. *Generic* markup adds information about the logical components of a document. In order to add markup to a text we need a precisely defined notation. Such a notation is called a *markup language*. The basic elements of such a language are called tags.

A markup language defines *tags* that group text and affect the way specific parts of a document will be rendered. In certain cases it is possible to define *macros*, that is, new tags that have the combined functionality of *primitive* tags. There are several markup languages that are widely used today. These include TeX, DocBook, and HTML and macro packages like LaTeX. However, in a way all these markup languages are descendants of SGML.

In what follows we will give a brief overview of SGML and XML. Then, we will discuss page description languages in some details, and we will continue with an overview of some very popular markup languages.

DOI: 10.4018/978-1-7998-3479-3.ch077

BACKGROUND

The *Standard Generalized Markup Language* (SGML) is the International Organization for Standardization (ISO) standard for document description [see (ISO-Standard, 1986) and (van Herwijnen, 1990)]. SGML is actually a meta-language that allows people to create markup languages. Typically, an SGML document consists of a file that contains marked-up data, the SGML declaration, and the document type definition (DTD). The SGML declaration specifies which characters and delimiters are used. For example, it is common to use the characters <, >, and /> as delimiters. And this why it is so common to see tags like <intro> and </intro>. Also, the The SGML declaration specifies which character set (Unicode or other) is used. Figure 2 shows an SGML Declaration for HTML 3.2. The DTD specifies how one can markup a class of documents. In particular, it defines the structure of a document and it is written in SGML. In general, no two different document classes have the same structure. Figure 1 shows a very simple DTD.

Figure 1. A very simple DTD from (Syropoulos, Tsolomitis, & Sofroniou, 2003).

```
<!ELEMENT first_name (#PCDATA)>
<!ELEMENT last_name (#PCDATA)>
<!ELEMENT profession (#PCDATA)>
<!ELEMENT name
(first_name, last_name)>
<!ELEMENT person
(name, profession*)>
<!ELEMENT scientists (person*)>
```

Today there are a few projects that are directly based on SGML. The *Text Encoding Initiative* (TEI) is such a project whose aim was to create software-independent methods for encoding humanities data in electronic form (TEI: Text Encoding Initiative). Docbook is another markup language based on SGML that was designed for technical documentation (DocBook Version 5.2, 2019). However, the current version of DocBook is an XML application.

The eXtensible Markup Language (XML) [see (Bray, Paoli, Sperberg-McQueen, Maler, & Yergeau, 2008) and (Harold & Means, 2009)] is a subset of SGML. The goal of XML is “to enable generic SGML to be served, received, and processed on the Web in the way that is now possible with HTML.” XML has been used to design the file formats of many office-productivity tools including the Office Open XML format (Standard ECMA-376, 2016) and the Open Document Format for Office Applications (OASIS Standards, 2011). The Open Document Format is also the ISO/IEC 26300:2006 standard.

An XML document consists of a DTD and a data file. For example, if one uses a DTD like the one shown in figure 1, then she can create a valid XML document like the one shown in figure 3. Note that the various <something> and </something> pairs are called *elements*. One of the differences between SGML and XML is that the later uses Unicode’s UTF-8 encoding as the default character encoding. In addition, since XML is a subset of SGML, it does not “understand” a number of SGML declarations, constructs, and entity declarations.

PAGE DESCRIPTION LANGUAGES

A page description language (PDL) describes the appearance of a printed page not in the form of an image file (e.g., a PNG file) but in notation specifically designed for this purpose. In general, a PDL is used to describe what goes on each page of a document (letters, graphics, color, etc.). There are many PDLs but three of them are still used widely today: PostScript, PDF, and PCL.

PostScript

PostScript® (PostScript Language Reference, 3rd Edition, Adobe) is a simple interpretive programming language with powerful graphics capabilities. A program in this language is a description of document that is generated by composition system and which can be transferred to printing device or used to have a look at the final product. The description is high-level and device-independent. PostScript is Turing-complete, which means that it can be used to perform a wide range of computing tasks.

PDF The Adobe Portable Document Format (PDF) is the native file format of the Adobe® Acrobat® family of products. These products have been designed so to allow users to exchange and view electronic documents easily and reliably, independently of the environment in which they were created. In 2008, PDF-1.7 became an ISO standard (ISO 32000-1:2008, 2008). As PDF has become the lingua franca of the printing industry, nowadays, most printing devices can natively accept and process PDF documents. A PDF file is structured as a series of possible nested objects and streams. Figure 5 shows a PDF file that corresponds to the PostScript file shown in figure 4. Note that the PDF file has been transformed so make visible all relevant details and also it has been edited so to fit on a single page, nevertheless, the structure of the file is pretty obvious.

Although the PDF format is extremely popular today, still we cannot be sure whether someone in 100 years from now will be able to read a PDF file! This is the reason ISO created a few standards that describe a version of PDF specialized for use in the archiving and long-term preservation of electronic documents. These standards are collectively known as PDF/A.

PCL

PCL is a PDL created by Hewlett-Packard (PCL5 Printer Language Technical Reference Manual: Part I, 1992). The language was designed so to provide an economical and efficient way for application programs to control a range of printer features across a number of printing devices. PCL commands are compact escape sequence codes that are embedded in the data stream that is supplied to the printing device. This simply means that PCL files are non-human readable in any possible way. Having a binary format minimizes both data transmission and command decoding overhead. Although this feature was particularly appealing in the 1990s, today it is almost irrelevant. And this is why PCL has remained a PDF that has not gained the status of PostScript and PDF.

XML-BASED DOCUMENT FORMATS

As was noted in the background section, there are many XML-based document formats. In particular, both Microsoft Office and LibreOffice, which are the most popular office productivity suites, use as their native file format XML-based files. In figure 6 we show the simplest possible workbook that can be opened by Excel. However, the native format that these productivity suits accept is a bit more complex than this simple file. In particular, the native document files produced by Microsoft Office have the .docx file extension, while native document file produced by LibreOffice have the .odt file extension.

Figure 6. The simplest possible workbook that can be opened by Excel.

```
<?xml version="1.0"?>
<?mso-application progid="Excel.Sheet"?>
<Workbook
  xmlns="urn:schemas-microsoft-com:office:spreadsheet"
  xmlns:ss="urn:schemas-microsoft-com:office:spreadsheet">
  <Worksheet ss:Name="Sheet1">
  </Worksheet>
</Workbook>
```

Both file types are in fact archives or, more specifically, zipped files. Figure 7 shows the files and folders that are used to save all required information. Naturally, if a document includes images or any other permissible media file, these are stored in the archive.

Figure 7. Directory structure of common XML-based document files.

DocBook has been designed to allow people prepare technical documents easily. The current version of DocBook (version 5.2) is an XML application. Unlike the office productivity file formats, it is relatively easy to manually create a DocBook document. The first thing one has to specify in a plain text file that will contain the markup is the file header. The header for version 5.0 of DocBook is shown below:

DocBook elements can be divided broadly into these categories:

- A *set* may contain one or more books.
- A *book* consists of a dedication page, a table of contents, parts, chapters, etc. Chapters are considered *components* while parts and reference sections are considered *divisions*.
- *Sections*, which subdivide components. There are several sectioning elements: from <sect1> to <sect5>. In addition, one can use the <section> element which can be nested, that is, one can have a <section> into another <section>, etc.
- *Meta-information* elements that provide the <title> of a document, its <author>s, etc., and are included in an <info> element.
- *Block* elements appear immediately below component and sectioning elements. They can be divided into a number of categories: lists, admonitions, line-specific environments, synopses of several sorts, <table>s, <figure>s, <example>s, etc.
- *Inline* elements are used to mark up running text. For example, they can be used to change the use of a font, but they do not cause line or paragraph breaks.

Figure 9 shows the skeleton of a complete DocBook article.

Figure 8. The header of a typical DocBook file

```
<?xml version='1.0'?>
<!DOCTYPE book PUBLIC "-//OASIS//DTD DocBook V5.0//EN"
"http://www.oasis-open.org/docbook/xml/5.0/docbook.dtd">
```

There are several methods to print a DocBook document. One of them makes use of eXtensible Stylesheet Language Formatting Objects (XSL-FO) (Pawson, 2002). The user invokes `xsltproc`, a command line XSLT processor. The XLST (eXtensible Stylesheet Language Transformations) is a language for transforming XML documents into other XML documents or other formats (e.g., HTML or XSL-FO). The final XSL-FO file can be printed using an XML-FO processor [see (XSL-FO Processors, 2014) for a list of XML-FO processors].

XHTML is a reformulation of HTML 4 as an XML 1.0 application (XHTML™ 1.0 The Extensible HyperText Markup Language (Second Edition), 2002). HTML 4 is an SGML application as were all previous versions of HTML. Since the current version of HTML is HTML 5, we will not say more about either XHTML or previous versions of HTML.

WEB-ORIENTED DOCUMENT FORMATS

There are a few more notable document formats that are used widely for the creation of digital documents.

HyperText Markup Language 5

The prefix hyper- generally means “above” or “beyond,” thus hypertext is something that goes beyond the limitations of ordinary text (e.g., it can be non-sequential). Hypertext is text which contains links to other information. The term was coined by Theodor Holm “Ted” Nelson around 1963. Software programs such as dictionaries and encyclopedias have long used hypertext in their definitions allowing readers to quickly navigate content. HyperMedia is a term used for hypertext which is not constrained to be text: it can include graphics, video and sound, etc. Ted Nelson coined this term too.

Tim Berners-Lee created what we call the Web while he was working at CERN. He created HTML and the HyperText Transfer Protocol (HTTP) and designed and implemented the first web browser. On October 1991 “HTML Tags” was made available. A description of version 2.0 of HTML was published on November 1995. HTML 3.2 was published on January 1997. HTML 4.0 was published on December 1997. HTML5 was published on October 2014 while HTML 5.1 was published on November 2016. The latest version of HTML5 is HTML 5.3 and its specification was published on 18 October 2018 (HTML 5.3: W3C Recommendation, 2018). Figure 10 shows a sample HTML5 file. Let us briefly describe the structure of an HTML5 file.

An HTML5 file consists of three parts: the `<header>`, the `<body>`, and a document identification line. The last part is just `<!DOCTYPE HTML>`. The `<header>` is where authors put the title of the document, meta-information (e.g., which character set is the default, keywords, etc.), and where the document loads external files that provide additional functionality [e.g., JavaScript code or Cascading Style Sheets, which is a “simple mechanism for adding style (e.g., fonts, colors, spacing) to Web documents” (Cascading Style Sheets: Home Page, 2019)]. The `<body>` of the document contains the content of the

Figure 9. The skeleton of a DocBook file

```

<?xml version='1.0'?>
<!DOCTYPE book PUBLIC "-//OASIS//DTD DocBook V5.0//EN"
    "http://www.oasis-open.org/docbook/xml/5.0/docbook.dtd">

<article>
  <info>
    <title>My Article</title>
    <author><honorific>Dr</honorific><firstname>Apostolos</firstname>
      <surname>Syropoulos</surname></author>

</article>

```

document. Note that we say the content and not just the text since one can have just video, an audio clip, an animation, a computer game, etc., in the <body> of an HTML document.

The first versions of HTML were designed so to be able to render text with some pictures. However, it was soon made clear that one could have videos, animations, sounds, etc., in a Web page. Since it was not possible to directly add this content, many software developers and companies created browser extensions or plugins that allowed different kinds of content to be included in a Web page. Unfortunately, not all plugins worked on all computer platforms. For example, the Adobe Flash plugin is not available for Android thus making it impossible for millions of users to browse Web pages that include Flash content. This and other similar reasons was the driving force behind HTML5, which includes all relevant tools and technologies to create Web pages that do not depend on external plugins.

In general, HTML documents can be interactive since one can embed JavaScript code thus “allowing” a Web page to react to user input (i.e., mouse movements, keyboard strokes, etc.). This of course is totally new form of document and one that is enhanced every single day.

ePUB (EPUB 3.2, 2019) is a document format similar to Microsoft’s .docx. The difference is that an ePUB archive consists of HTML files. One can say that an ePUB file is actually a Web site in a box. There are several tools to create ePUBs including Google Docs and the tex4ebook tool-set.

Figure 10. Sample HTML5 file. The arrows are used to annotate each line

```

<!DOCTYPE html> ← document type
<html> ← beginning of document
<head> ← beginning of head
<meta charset="UTF-8">
<title>Greetings</title> ← the title
</head> ← end of head
<body> ← beginning of body
Hello World! ← document contents
</body> ← end of body
</html> ← end of document

```

LaTeX

LaTeX [see (Lamport, 1994) and (Syropoulos, Tsolomitis, & Sofroniou, 2003)] is document preparation system that runs on top of TeX (Knuth, 1984), which is a typesetting language designed and implemented by Donald E. Knuth. Document preparation using LaTeX is task where the user concentrates on the logical structure of the document and not on how each part should look like. The latest approach is known in computer jargon as WYSIWYG (what you see is what you get). Clearly, the logical approach to document preparation is employed when preparing documents using DocBook, HTML, TEI, etc. Figure 10 shows a typical XeLaTeX source file. This is a modern variant of LaTeX where one has to use XeTeX to process input files. This is a modern variant of TeX that can natively accept Unicode input and that can use OpenType fonts, something not possible until some years ago. When preparing a LaTeX document it is advisable to use some special editor that can assist you in the preparation process. However, there are a few GUI systems that allow one to prepare a document and which emit LaTeX files. Such a system is LyX (LyX: The Document Processor, 2018) and figure 12 shows how the LyX's GUI looks like.

Figure 11. A typical XeLaTeX input file

```
\documentclass[a4paper]{article}
\usepackage{xltextra}
\usepackage{unicode-math}
\begin{document}
\setmainfont[Mapping=tex-text,Ligatures=Common]{Minion Pro}
\setsansfont[Mapping=tex-text,Scale=MatchLowercase]{Myriad Pro}
\setmonofont[Scale=MatchLowercase]{UM Typewriter}
\setmathfont[Scale=MatchUppercase]{Asana Math}
\title{My Title}
\author{Anastasios Dimou}
\maketitle
\secgction{A section}
\begin{displaymath}
\alpha^2+\beta^2=\gamma^2.
\end{displaymath}
\end{document}
```

Similar to an HTML document, a LaTeX document has three parts (see figure 11). The first part is the header where one declares the document type she intends to prepare, the default font size, paper size, etc. For example, the following header

```
\documentclass[a4paper,11pt]{article}
```

specifies that we are going to prepare an article on a A4 paper using 11 point as the default font size. What goes between the header and the command that follows

```
\begin{document}
```

is called preamble. There the user specifies which external macro packages should be loaded. These packages provide additional functionality to LaTeX and can be used to specify a custom paper and text

Figure 12. A screenshot of LyX in action

size, to modify the final layout, etc. Finally, what goes after the `\begin{document}` command is our text interspersed with formatting commands and/or structural markup commands.

As can be seen in figure 10, LaTeX markup is bit different but the principle is the same. Wikis are also written in a rather “strange” markup language.

Wikis

Wikis are Web pages where people write about something and others are usually allowed to modify the content in order to improve its quality. The idea was pioneered by Wikipedia, the free encyclopedia (wiki is Hawaiian for “fast; quick”). Wiki markup (Help:Wikitext, 2019) is a simplified form of markup. For example, heading are specified as follows:

```
==== Heading 4 ====
```

What goes inside the equal signs is the heading and the number of equal sign should be used to write sections, subsections, etc. A heading with only one equal sign, should be used for the title of a document. To enter a horizontal rule, one has to enter `----`. In HTML one get the same by entering `<hr/>`. In addition, one can use a number of HTML elements to format a Wiki page.

SOLUTIONS AND RECOMMENDATIONS

There are many different electronic documents types that have been designed to ease the process of creating such documents. Opting to use one tool or one system over some other is purely a matter of taste.

Some people feel more comfortable with GUIs whereas others prefer to write documents and mark up together. However, for long documents and very serious work, we believe the second approach is more reasonable. After all, one should care about she writes and how she writes something.

FUTURE RESEARCH DIRECTIONS

Many problems related to the preparation of digital documents have been properly solved. However, there are still problems that have not been solved completely or properly. For example, the preparation of traditional Mongolian text is something that needs our attention. Also, it is quite possible that new types of media may appear and these should find their way in our electronic documents. The advent of JSON may make it necessary to create document formats based on this technology. *Active documents* (Kohlhase, 2012), that is, digital documents augmented with embedded services that activate the content for interaction and adaption, is another interesting research direction. These documents reify the knowledge contained in a document. Thus a mathematical active document could include exercises that could be solved by the reader while reading the document. In addition, the document reader could assist the person reading the document to solve the exercises.

CONCLUSION

We have presented digital documents and their general characteristics. Also, we described in some detail the most important formats of digital documents and how one can structure such a document. Naturally, we omitted to mention a few formats (e.g., the Rich Text Format), however, we concentrated on what we thought are the most important milestones.

KEY TERMS AND DEFINITIONS

CLI: Command line interface is a way to run programs from a Unix shell or the Windows command prompt.

GUI: Graphical user interface is a graphical interface that is used to communicate and operate a computer program. Most computer programs come with a GUI since almost all users are accustomed to the use of the mouse.

Markup: A technology that has been developed for creation of digital documents. The text of a digital document is interspersed with markup elements that are either semantic or typographic annotations.

Digital Media and New Forms of Journalism

INTRODUCTION

This chapter analyses the role and operation of digital media, the impact of digital technology on the media sector and new forms of journalism that have emerged in the digital era. With its origins in the 1990s, digital technology has been embedded in the media sector for over two decades. These crucial years saw the rapid development and evolution of *digital technology* to *smart technology* and then to the *interactive format* of Web 2.0, which decisively altered media operations, content and format. This chapter aims to define and describe *digital media* and other related terms, while also shedding light on *new forms of journalism* that arise from the widespread adoption of digital technology. These may include (but are not limited to) *Virtual Reality (VR) journalism*, *drone journalism*, *selfie journalism* and *robot journalism*. Finally, this chapter offers an academic overview and understanding of the issues surrounding the way in which technological disruption transforms old habits and practices in the newsrooms, leading to innovative storytelling that transcends time and space.

BACKGROUND

The term *digital media* is used to refer to digitalized (information or other) content that can be transmitted via the internet and/or a computer network. Initially, this content could (potentially) include text, audio, video and/or graphics, although since the early 2000s this variety of elements has been enriched by new forms of journalism emerging from a range of technological trends, particularly the rapid spread of *smart technology*.

In the early days of Web 2.0, users could locate media content through the internet; however, this content offered the same information, in terms both of quantity and quality, as the traditional media, whereas new content was available only via paid subscription platforms (van der Wurff, 2008). Since then, media have converged at spectacular speed: from smartphones to radios, television sets to tablets, newspapers to computers, the audience increasingly moves between an ever-extending menu of media platforms (Cushion & Sambrook, 2016). The notion of digitally converged media technologies has been the object of widespread attention since the 1990s, initially focused on the convergence of broadcast television and the networked computer, later evolving to include all media entities.

One of the most widely observed consequences of the growth in digital media is audience fragmentation. As more offerings are delivered on broadband networks and more choices are available on-demand,

DOI: 10.4018/978-1-7998-3479-3.ch078

patterns of consumption become more widely distributed (Webster & Ksiazek, 2012). Furthermore, media convergence in the digital age is frequently used both in the academic field and the media industry to denote the ongoing restructuring of media companies as well as to describe developments in media forms, distribution and consumption. The use of the concept has developed from being mainly connected with digitalization in media technology to also include elements of the ongoing process of integration, combination, competition and divergence (Appelgren, 2004).

Although the rapid evolution of digital media raised questions regarding the future survival of traditional media, the latter still constitute a significant part of the media system. The co-existence of traditional and digital media brought forward the notion of *hybridity*. Hybrid media, developed in the late 1990s, due to the elusive progress of digital technology, rely heavily on interaction and could be described as the result of the deep remixing of previously separate media techniques and languages (Manovich, 2007). Chadwick, Dennis & Smith (2016) describe the hybrid media system as a system built on interactions among older and newer media logics, where logics are defined as bundles of technologies, genres, norms, behaviors and organizational forms. Actors in this system are articulated by complex and ever-evolving relationships based on adaptation, interdependence, concentrations and diffusions of power. Actors create, tap or steer information flows in ways that suit their goals and in ways that modify, enable or disable others' agency, across and between a range of older and newer media settings (Chadwick, 2013, p.4).

FOCUS OF THE ARTICLE

Until recently, most digital media were focused on converting analog data/footage into digital. However, in recent years they have developed distinctive capabilities of content management and became more accessible to a growing global audience that seeks information online. According to the Digital Future Project annual study (2018), 49% percent of users go online to look for news at least daily, and 70% of users go online for news at least weekly. Moreover, the emergence of social media as consumers' primary news source, the extensive use of mobile platforms and the advent of complex technologies such as Virtual Reality (VR) and Artificial Intelligence (AI) are paving the way for new forms of journalism that are shaping the future of the industry. Apart from VR and AI, drones and bots are also expected to play an important role in the nearby future by exploring new reporting frontiers. Drones are offering unique visual perspectives and assist journalists in filtering and authenticating their news stories whereas bots are changing the way news are delivered by providing voice messages, news bulletin or even breaking news to consumers (Veglis & Maniou, 2019). To this end, digital media are evolving in a dynamic way, entering a new era, where new technological trends such as drones, bots and smart glasses bring new opportunities for experiencing and exploring new kinds of journalism with distinctive features, traits and values.

VR (Virtual Reality) Journalism

A relatively recent development in the realm of digital journalism is *VR(virtual reality) journalism*, immersive journalism or 360 journalism, referring to the production of news in a way that replicates either a real or imagined environment and allows users to gain first-person experiences of the events or situation described in news stories while at the same time interacting with the environment. The fundamental idea of this new form of journalism is to allow the participant, typically represented as a digital avatar, to enter a virtually recreated scenario representing the news story. Today, 360° videos can be produced

with little technical expertise, using relatively inexpensive cameras, and posted on Facebook, Instagram and/or YouTube, allowing pieces to go viral while dramatically cutting their delivery cost. Meanwhile, the cost of headsets that deliver an even more realistic experience continues to fall (Mabrook & Singer, 2019). VR journalism is gaining widespread attention since it has the potential to enhance storytelling by offering the audience experiences and environments that traditional media could only hint at; it can also encourage attitude and behavior change to a greater extent than content produced for other platforms (Karlin B, Kim, H., T., Kelly, R., Blakley J., Brenner, C., & Riley, P., 2018). It should be emphasized, though, that this new form of journalism is best used for stories in which images are lacking because access is denied or where being in the actual space deepens one's understanding of a story beyond a written narrative, photos or regular video.

Selfie Journalism

The flourishing of social media have also significantly affected the media field, leading to the rise of *selfie journalism*: the practice of sharing and, thus, distributing to a global audience highly personalized information/stories/moments/events, following the vast growing tendency for people to broadcast themselves (Maniou & Veglis, 2016). Selfie journalism could be described as a new tendency in participatory and citizens' journalism, exercised via mobile devices and based on the practice of posting self-photographs (and/or videos) in the new media and thus reproducing content, not based on isolated objects/people/images, etc., but on artefacts framing the 'author' of the photograph. These artefacts (either objects/premises and/or other people) mostly constitute elements of the author's private life, which, thus, becomes intentionally public, aiming to attract other people's attention and provoke (mainly positive) reactions (Maniou, Panagiotidis & Veglis, 2017).

Network Journalism

The proliferation of social media and the participatory and interactive characteristics of the networked digital media have paved the way for another new form of journalism that draws on the active role and collective intelligence of members of the public. In *network journalism*, professional journalists and members of the public cooperate to produce the best stories by collaborating, corroborating, correcting and ultimately distilling the essence of the story that will be told; as such, the basic characteristics of network journalism are convergence, interactivity, customization of content and hypertextuality (Deuze & Bartoel, 2001). Countless citizen journalists contribute with their reports, images, information and opinions, making it possible for the practice of journalism to broaden the scope and diversity of its sources (Van der Haak, Parks & Castells, 2012).

Drone Journalism

The flourishing of technology is also influencing the role of drones in journalism, offering opportunities for exploring new forms of storytelling and reaching new places (Figure 1). Hovering over hostile environments and surfaces of land or water unapproachable by other aircraft, drones can diminish the distance between the audience and the subject, change and enhance the viewer's perspective in a number of distinctive ways. Drones can "pan" 360 degrees like any other camera, but if they are pointing down vertically, the rotating or "orbital" shot can circle nimbly around its subject. They can "fly-through" a

restricted space such as an archway, or dramatically “reveal” with a “pedestal” shot, rising or dropping (Adams, 2018).

These small remotely-guided aircraft, formally known as unmanned aerial vehicles, have evolved into a significant newsgathering tool for journalists that can also be combined with all the other contemporary media technologies such as VR journalism and provide footage that could not be obtained in any other way. In the years to come it is expected that drones will be equipped with environmental and pollution sensors or image recognition and crowd counting software thus helping journalists scrutinize official data, verify information or reveal new stories. Drone journalism constitutes an innovative new form of journalism that brings news perspectives into the field, but still needs to overcome a complex set of ethical and legal issues related to privacy and state restrictions regarding airspace regulations.

Figure 1. A picture taken with a drone to show the effect of climate change on the second-largest lake in Bolivia (Credit: Josh Haner/The New York Times)

Robot Journalism

Artificial Intelligence, where computers learn independently over time to improve outcomes, is developing algorithms to automatically generate news from structured data without human interference. This has led to the emergence of a new form of digital journalism, widely known as *robot journalism*, automated journalism or algorithmic journalism. This form of journalism is widely integrated into newsrooms, transforming the traditional practices of gathering, producing and disseminating information. The most common fields of use are finance, sports and election results. Paired with data storage, an algorithm

retrieves appropriate data and arrays them in accordance with its intended purpose. Afterwards, it structures a narrative and creates a story using natural language. Algorithms designed by human facilitate this process. In this sense, a robot utilized in journalism can be considered a semi-autonomous system. The final step in the process of writing news stories is to publish them (Kim & Kim, 2018). Apart from generating stories based on statistics and numerical figures, robot journalism is already used for creating video or photo displays to accompany text stories, driving better content recommendations. News organizations are increasing using ‘bots’ to deliver updates to smartphones and to interact with users in social media and send them customized content. As technology develops, robot journalism is likely to move into increasingly more challenging areas. The stakes are higher, though, when those bots speak for organizations that bill themselves as trustworthy sources of information. Misleading audiences, even accidentally or for only a moment, can damage a newsroom’s credibility (Heckman, 2018).

Data Journalism

The advent of technology is also helping journalists make sense of an enormous amount of complex data, to report on them and produce comprehensive and compelling stories through engaging infographics. *Data journalism* is a new form of journalism, referring to the use of online tools and open source software to rapidly scrape, filter, analyze and visualize stories in interactive features, mobile apps and maps (Howard, 2014). This new form of journalism, combining the skills and techniques of media professionals with the data analysis and programming skills of data analysts, is mainly used in investigative stories aiming to reveal corruption and hold the powerful to account.

SOLUTIONS AND RECOMMENDATIONS

The evolution of digital technologies and social media platforms have made it possible for journalists to gather, produce and disseminate stories in an innovative, fast and interactive way. Although acceleration seems to be the dominant trend in this era of instantaneous journalism, many media professionals and academics claim that digitization has wrought havoc on investigative journalism and stress the need for slow journalism which puts the emphasis on in-depth reporting, long form storytelling and the quest for nuances and perspectives.

As Le Masurier (2015, p.143) points out, *slow journalism* requires time for deeper reflection and/or investigation about an original subject, avoids sensationalism, is ethical in the treatment of subjects and producers, and uses verifiable and traceable sources and transparent methodology. Instead of desperately trying to compete with social media in a 24/7 news production process with continuous deadlines, slow journalism takes the time to research, double check the information, provide context to readers and make sure that it adheres to the fundamental principles and ethical values of quality journalism. Slow journalism can embody all the innovative digital tools and social media available in order to produce the best possible result, but it goes far beyond this. By slowing down, journalists can produce long-form multimedia stories – sometimes in cooperation with colleagues from other media organizations – that allow consumers to engage with complex stories that were not told at all or gained little media attention and journalists to present more points of view and add context to complex subjects. It goes without saying that slow and investigative journalism can certainly co-exist with all the other forms of journalism, but it costs time and money, since some stories may take months of investigation. This is one of the reasons that most media organizations have turned their backs on slow journalism. On the other hand,

slow journalism offers a deeper understanding of current and important issues and offers critical thinking that many readers are willing to pay for, making this investment worthwhile. Most of all, slow journalism constitutes a creative response to the crisis of quality journalism, since it adheres to the principles of truthfulness, accuracy, objectivity, impartiality, fairness and public accountability.

FUTURE RESEARCH DIRECTIONS

Digital media are evolving in a dynamic and innovative way and it is no exaggeration to say that the current innovative forms of journalism may be considered outdated in a short period of time. Future and emerging trends in digital media and journalism are expected to evolve around smartphone technology, social media platforms and advancements in AI. As news continue to shift to a digital format, *Augmented Reality (AR) journalism*, a technology that allows a user to continue to see and hear the surrounding world but with additional sights and sounds that are synchronized to the exact location relative to a user's three-dimensional (3-D) orientation to a geographic locale, seems to be an emerging trend (Pavlik & Bridges, 2013). Using new types of glasses or contact lenses, AR journalism introduces a digital overlay into the existing reality, bringing news consumers closer to the story and enriching journalism in a new and exciting way. In their typology of the stages that AR's development is following, namely (1) initial research design and development of AR technology completely outside the realm of journalism and media field, (2) early evolution of AR into a form that could be applied to other fields of human endeavor and (3) effective utilization of AR in journalism and media organizations for several reasons. Pavlik & Bridges (2013) predict a fourth stage of development during which journalism and media organizations will fully integrate AR as a routine narrative (Figure 2), allowing the audience to 'experience' the news, rather than just reading or observing them.

Figure 2. Stages of augmented reality (AR) development (Pavlik & Bridges, 2013)

Conversational journalism, voice-powered AI that allows the consumer to interact with a bot, is another future trend. Conversational journalism is mainly based on the advent of chatbots, namely conversational bots that provide answers to questions about news events, people, and/or places. Chatbots offer a new interface for communicating with a story and help journalists tell their stories differently or collect information from readers. Their unique characteristics, such as the ability to have some kind of conversation with the user, are expected to be exploited in the near future (Veglis & Maniou, 2019). The advances in the sector of the Internet of Things (IoT), are also expected to have a serious impact on journalism as online media will extend to devices such as voice assistants, wearables, home automation objects and a whole host of elements we use in our daily lives (Salaverría, 2019).

Apart from technology, though, the need for accurate and quality journalism is also likely to pave the way for new forms of journalism that emphasize in-depth reporting and providing information and analysis that are unavailable elsewhere.

CONCLUSION

Digital media have developed rapidly in recent years and advances in technology have paved the way for the implementation of computational and automatization processes in all aspects of mass communication. Digitalization, social media platforms, smartphone technology and AI software improve the workflow speed of journalists, add value to their stories and provide consumers with innovative, engaging and in-depth storytelling. New media technologies are becoming an integral part of the digital journalist's toolbox and new forms of journalism are reshaping the media field. For example, AI robotic presenters that can imitate news anchors' voices, lip movements and expressions are already introduced by China's Xinhua News Agency. New York Times have already adopted AR in their digital storytelling extending their stories beyond the inches of a screen and offering their audience the chance to interact with augmented reality content. The next quarter century, the intersection of journalism and technology is expected to deepen and lead to major technological, social and professional innovations that will continue the profound transformation of journalism, quite possibly at an even faster pace than in recent years, generating opportunities as well as new challenges (Salaverría, 2019). To survive in this competitive environment, media organizations will need to adapt and incorporate these changes, without losing sight of their primary aim, to provide their audiences with the information and context they need to make sense of the world.

KEY TERMS AND DEFINITIONS

Conversational Journalism: A term used to refer to voice-powered Artificial Intelligence that provides answers to questions given by users.

Data Journalism: The use of software and online tools in order to analyze and visualize a large amount of complex data.

Digital Media: Digitalized information or other content that can be transmitted via the internet and/or a computer network.

Drone Journalism: The use of remotely operated or autonomous drones to acquire pictures and videos that can enrich media content.

Hybridity: A mixed system including traditional, digital, and new media.

Interactivity: A term used to distinguish new from old media, which refers to the communication process between users and between users and computers, through the media.

Network Journalism: A term used to refer to professional journalists and other stakeholders cooperating to produce stories. Networks of professionals and citizens collaborate, corroborate, correct, and ultimately distill the essence of the story that will be told.

Robot Journalism: The use of Artificial Intelligence in order to develop algorithms that can generate news and stories from structured data.

Selfie Journalism: A term used to refer to a new tendency in participatory and citizens' journalism, exercised via mobile devices and based on the practice of posting self-photographs (and/or videos) in social media and thus reproducing content, not based on isolated objects/people/images, etc., but on artefacts framing the 'author' of the photograph. These artefacts (either objects/premises or other people) mostly constitute elements of the author's private life, which, thus, become intentionally public, aiming to attract other people's attention and (mainly) positive reactions.

Slow Journalism: A term used to refer to the kind of journalism that requires time for deeper reflection and/or investigation about an original subject, avoids sensationalism, is ethical in the treatment of subjects and producers, and uses verifiable and traceable sources and transparent methodology. Instead

of desperately trying to compete with social media in a 24/7 news production process with continuous deadlines, slow journalism takes the time to research, double check the information, provide context to readers and make sure that it adheres to the fundamental principles and ethical values of quality journalism.

Smart Technology: The term ‘smart’ is in fact an abbreviation for ‘Self-Monitoring Analysis and Reporting Technology’, although it is used with its actual meaning of ‘clever’ to describe any kind of available technology that allows users to connect with internet networks.

Virtual Reality Journalism: The term refers to the production of news in a way that replicates either a real or imagined environment and allows users to interact within this environment.

Data Journalism: Definition, Skills, Difficulties, and Perspectives

INTRODUCTION

The introduction of ICTs (Information Communication Technologies) at the last decade of the 20th century had a profound impact on almost every aspect of human activities. Journalism was one of the areas where ICTs had a significant impact, since it transformed the profession through the digitalization of the work process as well as the introduction of internet services (Veglis 2009). Today, the journalist is expected to have the ability to firstly employ many tools and services in order to be instantly informed about breaking news as well as current events, and secondly, use a variety of tools and applications in order to prepare and disseminate news articles (Veglis & Bratsas, 2017a). Many new types of journalism have emerged (algorithmic journalism, drone journalism, multimedia journalism, etc. (Diakopoulos, 2019; Ntalakas, Dimoulas, & Veglis & Bratsas, 2017a; 2017b; Tu, 2015)) along with data journalism (Gray, Chambers, & Bounegru, 2012), which require journalists to have special skills.

In recent years, data journalism has drawn significant attention in academic literature as well as in the area of new developments in digital news production (Hermida, & Young, 2017; Loosen, Reimer, & De Silva-Schmidt, 2017; Weber, Engebretsen, & Kennedy, 2018). Data journalism is now considered to be an established form of journalism. It has appeared gradually in the dawn of the new century. Many factors have contributed to the introduction of data journalism, but one of the most prominent is believed to be the availability of data in digital form. Another factor that contributed to its introduction was the availability of visualization and data management tools (Veglis & Bratsas, 2017a). Data Journalism is a journalistic specialty reflecting the increased role that numerical data has in the production and distribution of information in the digital era. Data can be the source of data journalism, and/or it can be the tool with which the story is told (Gray, Chambers, & Bounegru, 2012).

This chapter attempts to describe the state of data journalism today. The background section provides the historic evolution and definitions of data journalism. Next, the stages of data journalism are presented in detail, along with the necessary corresponding skills of the data journalist. Also, the various difficulties that the evolution of data journalism is facing are presented. Finally, recommendations and future research directions are briefly discussed.

BACKGROUND

Evolution and Definition

Although the term data journalism started to attract attention at the end of the previous century, initial examples of data journalism appeared quite early. According to Simon Rogers (currently data journalist and data editor at Google), the first example of data journalism was published at The Guardian in 1821, and it concerned the number of students who attended school and the costs per school in Manchester (Gray, Chambers, & Bounegru, 2012).

At the end of the 20th century, employing large datasets to write an article was difficult and required skills that went beyond the capabilities of the average journalist. To address these shortcomings news organizations in the United States and Great Britain began hiring programmers to work on novel news products (Parasie & Dagiral, 2013). Traditionally, journalists have relied on information provided by a variety of sources (governments, officials, research studies, etc.). Of course, there were some cases of investigative journalism where journalists were able to find resources to gather and analyze their own data and publish their results in articles (Veglis & Bratsas, 2017a). But things changed significantly as data gradually became more available online, along with efficient tools allowing anyone to analyze, visualize and publish large datasets (Gray, Chambers & Bounegru, 2012; Sirkkunen, 2011; Uskali & Kuutti, 2015).

Big data, the popular term for large datasets, was introduced into common usage during the last decade of the 20th century. It can be defined as datasets of a size which cannot be captured, curated, managed and processed by commonly used software running on standard personal computers (Snijders, Matzat & Reips, 2012). Is it quite obvious that there is a strong relation between big data and data journalism, since they have developed almost in parallel and data journalism is based/generated by big data (Veglis & Maniou, 2018).

The concept of data journalism is not new. It has been around since the beginning of the digitalization of news. Digital data has been utilized in news production since the late 60s in US newspapers (Parasie & Dagiral, 2012). Data journalism gradually emerged with the rapid introduction of ICTs and the availability of data in digital form. The term *data journalism* is synonymous with *data-driven journalism*, while the older term *computer-assisted reporting* has largely vanished since it was introduced at the early stages of computer history (Bradshaw, 2010). It is worth noting that in the case of data journalism there is an increased interaction between journalists and several other fields such as design, computer science and statistics (Thibodeaux, 2011; Veglis & Bratsas, 2017a).

The term data journalism is attributed to Simon Rogers who first mentioned it in a post to the Guardian Insider Blog (Knight, 2015). It can be viewed as a process that begins with analyzing and continues with filtering and visualizing data in a form that links to a narrative (Lorenz, 2010). It combines spreadsheets, graphics, data analysis and the biggest news stories (Rogers, 2008). It is fundamentally the production of news graphics and includes elements of design and interactivity (Bradshaw, 2010; Lorenz, 2010; Rogers, 2008). Megan Knight (2015) describes data journalism as “a story whose primary source or ‘peg’ is numeric (rather than anecdotal), or a story which contains a substantial element of data or visualization”.

Veglis and Bratsas (2017a) proposed a definition in order to better address the power of visualization and interactivity which are significant factors in data journalism. They defined data journalism as the process of extracting useful information from data, writing articles based on the information and embedding visualizations (interacting in some cases) in the articles that help readers understand the significance of the story or allow them to pinpoint data that relate to them.

Figure 1. Data Journalism workflow

Data Journalism Skills

Veglis and Bratsas (2017a) organized the data journalism workflow in six stages, namely: *Data Compilation*, *Data Cleaning*, *Data Understanding*, *Data Validation*, *Data Visualization* and *Article Writing*. The workflow model is depicted in figure 1. In order for journalists to be able to produce data journalism projects they need to process certain skills that directly relate with the data journalism stages. Next, we briefly describe each stage, as well as the corresponding data journalist's skills.

Data Compilation: A data journalism project begins in one of two ways: either the journalist has a question that needs data or has a dataset that needs questioning. The compilation of data can take one of the following forms: (i) data may be supplied directly by an organization (in some cases in the form of open data), (ii) data may be found with the help of advanced searching techniques, (iii) data may be compiled by scraping web pages, (iv) data may be collected by converting documents to other formats that can be analyzed, and (v) data may be collected by means of observation, surveys, online forms or crowdsourcing (Bradshaw, 2011). Data scraping is a process in which a software tool extracts data from a human-readable output that originates from other software (i.e. copying in a spreadsheet the content of a table which is included on a webpage). Also, there are free tools on the internet that allow users to convert documents to other forms that can be analyzed. For example, DocumentCloud is a web-based software platform created specifically for journalists to allow the searching, analyzing, annotation and publication of primary source documents used in reporting (Veglis & Bratsas, 2017b).

First of all, a data journalist has to be capable of generating ideas for data-driven stories and determining the relevant data that he/she needs for his/her research. Then, he must be able to find and acquire the data he is searching for in many ways. While web scraping may be considered as a more advanced skill that often depends on the web page technologies, the awareness of open data repositories and statistical platforms and databases is a crucial part for data retrieval, as governments, public sector bodies and analytics agencies tend to provide more and more open data lately. The data journalist must have a broad knowledge of all the corresponding national open data sources, at least, and how he can use them, in order to extract the data for his analysis. He should also know to extract data from social network APIs, like Twitter, as these can provide additional data directly related to a topic, or an entity, although they usually grant access to only a small amount of the most recent data (Veglis & Bratsas, 2017a).

Data Cleaning: Also known as *data scrubbing*, this is the process of detecting and correcting corrupted or incorrect records from a dataset (Wu, 2013). This can be accomplished by removing human errors and converting the data into a format that is consistent with other data the journalist is using. Typical examples include empty entries, duplicate entries, the use of default values to save time or where no information was held, incorrect formatting (for example words instead of numbers), corrupted entries or entries with HTML code, multiple names for the same thing and missing data (Bradshaw, 2011). Cleaning

data can be done in simple ways, for example, using find and replace commands or filters in spreadsheets. There are also specialized tools, like Google's OpenRefine, which is a standalone open source desktop application for data cleanup and transformation to other formats. The application's interface resembles spreadsheet applications and it can open files of various spreadsheet formats (Veglis & Bratsas, 2017a).

Data journalism skills are rather obvious in this step. The data journalist must be able to fluently use the most common data cleaning tools, spreadsheet software and SQL. He must also have in mind all the potential errors that could be included in the extracted dataset, in order to check and correct the records in an automated way. As each dataset may contain different kinds of errors, this skill needs continuous and repetitive effort with many datasets that require various data cleaning tasks.

Data Understanding: Datasets usually include various codes that represent categories, classifications or locations, and special terminology that it is not understood by journalists. Frequently further data is required for existing data to become meaningful and the journalist has to put them in the story context. The data journalist interviews not a person but the data, as he explores his initial ideas through them, using statistical tools. Spreadsheets, relational databases and more advanced software like R, Python, Ruby, NodeXL and network analysis are some of the main tools to find the story in the data, to investigate and analyse the data, to identify significant data trends and finally, to lead to insightful results and tell a compelling story.

Overall journalists must be data-literate, meaning that they must be able to consume knowledge, produce coherently and think critically about data (Veglis & Bratsas, 2017a). Additionally, journalists must possess statistical knowledge and computational skills, think of creative ways to channel data and also understand how to work with large datasets, how they were produced, how to connect various datasets and how to interpret them (Gray, Chambers, & Bounegru, 2012).

Data Validation: This stage includes the process of cross-checking the original data and obtaining further data from sources in order to enrich the available information (Silverman, 2014; Veglis, 2013). It is worth noting that, like any source, datasets cannot always be trusted since they come with their own histories, biases, and objectives. That means that journalists have to investigate issues like: who gathered it, when, and for what purpose, and how it was gathered (Bradshaw, 2011). This can be accomplished by investigating the history of the creation of the dataset, by finding references to the dataset or by using other sources of information that refer to the same subject (Silverman, 2014; Veglis & Bratsas, 2017a).

The data journalist needs to develop ways and skills to check and prove the correctness of the data used. Thus, data journalism skills are related at some level to the data compilation step, as the journalist must be able to search for data as well as its metadata, that is information about the data (e.g. author, date produced, updated, or published, etc). Usually, open data repositories from public sector provide adequate metadata and this is primarily a data publisher's task. However, the data journalist is responsible for checking and cross-validating the datasets and using only correct and updated data in his research. At some point, the data journalist acquires the experience and the skill of identifying the reliable sources and datasets, as well as what is missed or has to be further examined by outdated or unofficial resources.

Data Visualization: Data visualization is a modern branch of descriptive statistics that involves the creation and study of the visual representation of data. It is the graphical display of abstract information for data analysis and communication purposes (Cairo, 2012). Static data visualizations offer only pre-composed "views" of data. Interactive data visualization supports multiple static views in order to present a variety of perspectives on the same information. Important stories include "hidden" data and interactive data visualization is the appropriate way to discover, understand and present these stories. In

interactive data visualization, there is a user input (a control of some aspect of the visual representation of information) and the changes made by the user must be incorporated into the visualization in a timely manner (Veglis, 2015; Veglis & Bratsas, 2017a).

It is worth mentioning that infographics are also part of the static visualization. Infographics are graphic visual representations of data or knowledge, which are able to present complex information quickly and clearly (Smiciklas 2012). They are often used in newspapers, to show the weather, as well as maps, site plans, and graphs for statistical data (Veglis & Bratsas, 2017b).

There are many types of data visualizations. Heer, Bostock, and Ogievetsky (2010) defined the types (and also their sub-categories) of data visualization: (i) Time-Series Data (Index Charts, Stacked Graphs, Small Multiples, Horizon Graphs), (ii) Statistical Distributions (Stem-and-Leaf Plots, Q-Q Plots, Scatter Plot Matrix -SPLOM, Parallel Coordinates), (iii) Maps (Flow Maps, Choropleth Maps, Graduated Symbol Maps, Cartograms), (iv) Hierarchies (Node-Link Diagrams, Adjacency Diagrams, Enclosure Diagrams) and (v) Networks (Force-Direct Layout, Arc Diagrams, Matrix Views).

Today there are a lot of available online tools that can be used for creating interactive data visualizations. All of them are either free or offer a free version (except a paid one that includes more features). Some of the most widely used tools are CartoDB, Google Chart Tools, Google Fusion Tables, Tableau Public, Many Eyes, and Infogram. A complete list of the available tools can be found at <http://selection.datavisualization.ch>.

The visualization is a crucial part of the story and its presentation. The data journalist must be able to make insightful and illustrative visualizations, that highlight information that is not clear within the raw data and incorporate them harmoniously into the story. Apart from the ability of using sufficient tools for visualizing the data to transform a dataset into a powerful and insightful visualization, the data journalist needs to know, at first, the pros and cons of different methods of visualizing data, as well as to understand the relations within the data that have to be represented by a chart or diagram. Different chart categories may be used for showing a comparison, or a proportion, or a hierarchy, or a distribution, etc. Thus, the data journalist must have a clear story objective and select only from a few charts of his visualization quiver to represent the data.

Article Writing: The last stage in a data journalism project includes the writing of the news article. Depending on the intended publication medium, the article may include special characteristics (*e.g.*, external links, other articles or related material, multimedia content, mashups, static or interactive visualizations) in order to fully take advantage of the medium's potentials (Veglis & Bratsas, 2017a). The amount of text that is included in the data journalism article along with the visualizations may vary considerably. Specifically, we can have the case where the visualization supplements the text (which is quite extended) as well as the case where the visualization is the center of the project and the text plays a supplemental role, explaining parts of the visualization.

The data journalist must be able to present all the key points of his research and integrate them properly into a news story. All ideas and information have to be well presented and understandable to the audience, who are likely coming from non-statistical background, otherwise the story will have little effect, no matter how insightful or valuable it is. Feature and multimedia storytelling are also prerequisite skills. Finally, all the stages must be clear to the audience and the methodology of the data journalist needs to be reproducible, in order to be verifiable and repeatable.

DIFICULTIES

8

Although data journalism has been around since the beginning of the 21st century, it does not appear to have gained momentum (Veglis & Bratsas, 2017a; 2017b). It is common practice for data journalism stories to be categorized as less interesting stories, resulting in being published on inside pages, or as infographics, which relatively few people look at (Stoneman, 2015), and even fewer read through. Based on the above, it is quite obvious that data journalism does not appear to be near in becoming mainstream journalism (Veglis & Maniou, 2018).

There are several factors that contribute to this result. Data journalism projects require time in order to be developed, and time is something the media organization do not have today. Also, data journalism costs more than traditional journalism. The economic model of practicing data journalism is not yet quite defined (Gray, Chambers & Bounegru, 2012), and media organizations seem reluctant to invest on data journalism without seeing tangible circulation gains.

There is also the issue of the additional skills that journalists must process in order to be able to develop data journalism projects. The journalists seem quite unprepared in many cases for such tasks and expect media organizations to cover the cost of acquiring data journalism skills (Veglis & Bratsas, 2017a). Of course, young journalists are not expected to encounter similar difficulties (at least not to the same extent) since market demands, as far as journalistic skills are concerned, has forced journalism educators to adjust their programs in order to better facilitate the needs of the industry (Wenger & Owens, 2012). Currently, data journalism is taught in a limited number of journalism schools in Europe. Of course, this is something worth investigating more thoroughly in the near future. A recent survey, concerning the use of data journalism in Greece found a low penetration of data journalism practices in media organizations. Nevertheless, the majority of the journalists appeared to agree with the importance of working with data and was interested in acquiring more knowledge and skills concerning data journalism (Veglis & Bratsas, 2017a).

FUTURE RESEARCH DIRECTIONS

Tim Berners-Lee believes that “data-driven journalism is the future” and urges reporters to hunt for stories in datasets (Arthur, 2010). We are convinced that the Semantic Web and Linked Open Data will play a significant role in the evolution of data journalism. In the future, journalists should be able to comprehend and utilize advanced technologies which will include a more “intelligent web” (Bradshaw & Rohumaa, 2011). Semantic Web technologies, smart devices (smartphones etc.) and tools are continuously being transformed and upgraded. Data journalism ought to adopt these technologies. It is worth noting that Web 3.0 and open data can play an important role in the case of data journalism as they support the acquisition and validation of data which are the main source of data journalism.

One significant issue that needs to be addressed is the lack of online platforms that can support all stages of a data journalism project. Today, there are several online tools that can be used in different stages of a data journalism project. Each tool has its own unique interface and the journalist must spend time in order to learn how to use it effectively. Most of them do not offer any interconnectivity with other tools. Thus, the journalist spends a lot of time transferring data from one platform to another in order to exploit the strong points of each tool. In other words, the landscape is fragmented, and there is a lack of an integrated platform on which the journalists can work on all stages of data journalism projects. Data journalists can strongly benefit from the introduction of online platforms that will interface various

online tools that can be used in data journalism projects. This is a problem that media industry should address in cooperation with the informatics industry.

CONCLUSION

This chapter discusses the issue of data journalism. Data journalism is considered to be a journalistic specialty that is expected to flourish in the world of data that we are living in today. Data journalism stages were presented and discussed in detail, in conjunction with the skills that journalist ought to have in order to develop data journalism projects. Also, the difficulties that data journalism is facing are also examined. Finally, future perspective of this journalism specialty are also briefly discussed.

There is no doubt that the majority of the journalists today are not involved in data journalism projects, although they are willing to work on such projects in the future. Online journalists appear to be more involved and more motivated towards data journalism. Since there is an ongoing shift to online journalism (Cokley, Edstrom, McBride, & Ranke, 2015), many new developments in the area of data journalism are expected. In the continuously changing media landscape, where traditional media organizations are faced with stiff competition from social networking services as well as from citizen journalists, the degree of complexity that data journalism involves in its production may be an opportunity for professional journalists to gain back their popularity as well as their credibility.

KEY TERMS AND DEFINITIONS

Data Cleaning or Data Scrubbing: The process of detecting and correcting corrupted or incorrect records from a dataset.

Data Journalism: The process of extracting useful information from data, writing articles based on the information and embedding visualizations in the articles that help readers understand the significant of the story or allow them to pinpoint data that relate to them.

Data Scraping: The process in which a software tool extracts data from human-readable output that originates from other software.

Data Validation: The process of cross-checking the original data and obtaining further data from sources in order to enrich the available information.

Data Visualization: The graphical display of abstract information for data analysis and communication purposes.

Dataset: Is a collection of data that contains individual data units organized in a specific way and accessed by a specific access method that is based on the dataset organization.

Open Data: Is data that can be freely used, re-used and redistributed by anyone – subject only, at most, to the requirement to attribute and sharealike.

Exploring the Integration of User-Generated Content in Media Organizations Through Participatory Journalism

Theodora A. Saridou

Aristotle University of Thessaloniki, Greece

INTRODUCTION

The concept of user engagement in news production process has evolved during the last centuries to extend from early forms of participation in printed matters to wholly participatory platforms hosted by mainstream online media outlets. The initial steps of the 17th century (Boczkowski, 2005) were followed by practices like letters to the editor, newspaper ombudsmen and reader representatives, before Internet and World Wide Web (Web) spread made it possible for message boards and chat rooms to be implemented on news websites (Deuze, 2006; Gillmor, 2004; Singer et al., 2011). Nevertheless, it was the predominance of Web 2.0 that led to the radical transformation of the journalist-audience relationship (Reader, 2018; Sinton, 2018).

Remarkable quantities of user-generated content (UGC), basically in the form of text, photos, videos and graphics (Anderson, 2007), are produced and uploaded thanks to easy-to-use publishing tools, always-on connections and powerful mobile devices (Bowman & Willis, 2003). Meanwhile, citizen journalism activity through social media such as Facebook and Twitter is becoming increasingly relevant and important (Kim & Lowrey, 2015, p. 298) and anyone with something engaging to share can be a potential mass communicator (Moore & Hatcher, 2018). As Newman (2009) states, social media and UGC have fundamentally changed the nature of breaking news by contributing to the compression of the “news cycle”, putting more pressure on editors over what and when to report and creating an important extra layer of information and diverse opinion.

Technological developments, along with social and economic transitions (Moretzsohn, 2006), declined audience’s confidence in mainstream journalism (Hirst, 2011) and loss of advertising revenues (Franklin, 2014) provoke strategic redesign in media, challenging traditional concepts such as gatekeeping (Bruns, 2005). Thus, online media adopt tools and applications of participatory journalism, where users can -among others- comment on published stories, send their own digital material, discuss several issues and share articles in social networking sites. However, users’ involvement in making and disseminating news raises a variety of ethical, legal and responsibility issues, which force organizations to use quality assurance methods (Saridou & Veglis, 2016, p. 88).

This chapter aims to offer an in-depth description of the concept of participatory journalism, by providing a deep approach to the conceptual sense of this phenomenon, presenting an analytical framework of the audience engagement in online news production. The chapter seeks better understanding

DOI: 10.4018/978-1-7998-3479-3.ch080

of the adoption of UGC in media via different forms, tools and applications and during different stages of journalistic process. The problems organizations have to deal with when amateur content is involved with the professional content and the solutions chosen are investigated as well. Finally, future research perspectives are discussed.

BACKGROUND

Very early stages of audience's participation in news production process are rooted in the 17th century, when readers can write on the intentionally blank last page of "*Publick Occurrences Both Foreign and Domestick*", before passing it to someone else (Boczkowski, 2005, p. 141). During the next century, newspapers publish readers' letters to the editor, while later, in the 20th century, more active contact with the community takes place, via newspaper ombudsmen, reader representatives, focus groups and polls (Bowman & Willis, 2003; Deuze, 2006). Apart from press, both in radio and in television broadcasting, presenters receive phone-ins and text messages from audience members who provide information about breaking news or discuss on air (Gillmor, 2004). According to Nip (2006, p. 214), it is the public journalism movement in 1990's that aims to help democracy by connecting to the community, engaging individuals as citizens and helping public deliberation in search for solutions. At the same time, newspapers, which have already launched their online media counterparts, invite users to take part in discussion board and chat room conversations (Beyers, 2004). What's more, journalists' emails are often provided next to the stories and readers use them to indicate errors or make suggestions for further research.

With the proliferation of Information and Communication Technologies (ICT), technology determines the functional definition of a new form of journalism (Deuze, 2003). As Siapera and Veglis (2012) note, online journalism causes such fundamental and permanent changes on the face of journalism that it is difficult to imagine journalism being practiced exclusively outside Internet. Journalistic practice moves towards interactivity (Stovall, 2004), individuals look for and produce additional information (Singer et al., 2011) and the way they communicate with each other is revolutionized (Hess, 2013). Ward (2002) distinguishes three levels of interactivity at which consumers interact both with the news provider and with each other, while they also have the ability to become providers.

Except for constantly evolving technological developments, broader citizens' engagement in news production process is also favored by the conditions of the economic and social environment (Domingo et al., 2008; Paulussen, Heinonen, Domingo, & Quandt, 2007). As Hirst (2011, p. 15) notices, society believes that journalists fail in their duty to promote and protect public interest and, in such a context, part of the audience seeks for alternative forms of information outside traditional media and without professional mediation (Turner, 2010). In the years that followed, breaking events, such as the 9/11 attacks in the United States of America and the 7/7 attacks in London, triggered citizen journalism activities, motivating eye-witness amateurs to collect and upload photos and personal narratives from the places of interest on blogs and forums. Instead of being primarily journalistic-centered, online news is increasingly user-centered, so that citizens have a much greater input on it, with a qualitative leap in the presentation of their own stories, opinions and audiovisual material (García-Avilés, 2010, p. 251).

Gradually, media landscape faces a catalytic transformation under the prevalence of Web 2.0 as the average citizen can now create media content (Meraz, 2009, p. 123), in many forms, using quite plain portable devices, tools and applications. Audience members acquire the opportunity to take actively part in the production and dissemination of news. Literature shapes new concepts in order to describe professionals' and non-professionals' changing role in news process. Deuze (2003) argues that users

are prosumers (merging the terms *producer* and *consumer*), while Bruns (2005) focuses on produsage, where participants are simultaneously *producers* and *users*, working on the collaborative and continuous building of existing content. As a result, journalists' hegemony as gatekeepers seems to be threatened, since news can now be recorded not only by controlling information flow, but by harnessing the collective knowledge of a community as well (Bruns, 2008, p. 176). Gatekeeping turns to gatewatching, considering that journalists do not define, but watch the information flow stemming from a variety of sources, receive UGC and construct a final product (Bruns, 2008). In a similar vein, Boczkowski (2005) refers to gateopening, when users actively co-develop website content and traditional work routines are questioned.

Although the idea of mediated participation is part of the long-standing debate between cyber-optimists and cyber-pessimists (Spyridou, 2018, p. 2), it is accepted that the current new media era has seen a proliferation of UGC and an increasing participation by Internet users in public communication and newsrooms seemingly are keen to integrate UGC into ordinary news practice (Tong, 2015). Paulussen and Ugille (2008) argue that professionals are forced to share control of the news production process with users, as they are increasingly involved in creating content. Thus organizations are gradually redefining their work strategies, combining amateur content production with editorial control under a professional umbrella (Deuze, 2006).

"Participatory journalism" is the concept that best describes "the processes and effects of ordinary citizens' contributions to gathering, selecting, publishing, distributing, commenting on and publicly discussing the news that is contained within an institutional media product" (Singer et al., 2011, p. 15). In Siaper's view (2012), it is constituted a distinct species of journalism due to three elements: The first is readers' direct participation in the journalistic process, as they are provided the means to post their news articles, photos and opinions, so they are or can potentially become journalists themselves. Secondly, the news is organized on the basis of importance to those running the site rather than confronting to standardized values and the last one identifies an involved and overtly partisan stance toward the political process. The latter means that, because of the reliance of this journalistic form on readers than journalists, its stance vis-à-vis the political process is not the objective or at least detached one found in other, more mainstream forms of professional journalism.

Although the interchangeable use of the terms "participatory" and "citizen" is not rare (Bowman & Willis, 2003; Gillmor, 2006; Lewis, Kaufhold, & Lasorsa, 2010), it is however important to distinguish between the two forms of journalism, mainly based on the concept of control. Participatory journalism encompasses users' contribution in the news-making process, which is solicited within a frame designed by professionals, while in citizen journalism people are responsible for gathering content, visioning, producing and publishing the news product, but professionals are not involved at all (Nip, 2006). Therefore, participatory journalism takes place when content is co-created by journalists and users on an editorially controlled platform and when the content created by users elsewhere is then acquired and used by professional media outlets.

EXPLORING PARTICIPATORY JOURNALISM

Tools and Applications of Participation

News organizations adopt a range of tools and applications to integrate users' contribution into their websites. Participatory formats have not been classified in a single typology, while research has pointed

out that there is diversity not only in the way journalists manage participation, but also throughout news production process and in the effort needed by participants in order to engage.

Singer et al. (2011) focused on the opportunities that are provided to audience members in order to get involved in the different stages of news production process. Their study of leading newspapers and their respective websites in ten Western democracies indicates that in the initial information-gathering stage, named access/observation stage, organizations are reluctant to allow readers to set the news agenda, limiting the user's role to serving as a source of information or raw audiovisual content. Journalists mainly enable users to submit photos and video in order to receive material that they are unable to get in other way (Mast & Hanegreefs, 2015), while an almost complete lack of witness contributions is also recorded in some media organizations (Saridou & Veglis, 2016).

Moving to the selection/filtering stage, Singer et al. (2011) concluded that it is the most closed of all, as newspapers do not allow readers to take part in the gatekeeping process and decide what should be the main news product. However, in rare cases in which users are allowed a semblance of control over the selection and filtering of news, it takes place in areas separated from the main website, though supervised by the parent organization. Rather closed is the processing/editing stage as well, with only a few options for citizen stories, always subject to strict editorial control. When users can participate in content production, their engagement is limited to lifestyle topics, treated as news tips than stories and explicitly distinguished from professional job (Johnson & Dade, 2018). In the distribution stage, participation seems to be the limited involvement in the dissemination of news stories, performed usually through automated content ranking features and social media sharing options. According to Singer et al. (2011), it is the interpretation stage that offers most opportunities for participation, from simple tools, such as polls, to more engaging and effort requiring ones, such as forums and comments. Users are allowed to discuss the news content produced by professional journalists, who control and moderate the submissions.

Following a different categorization, Franquet, Villa and Bergillos (2011) identified four groups of tools that apply to different propositions within the communication process. These are discussion tools, which encourage debate and audiences can discuss, compare opinions and exchange ideas about the information; socializing tools for sharing content, where users' contributions are not put onto the news websites, as services operate outside the organization and usage conditions do not seem to be defined by it; contribution tools for acquiring public's images, texts and audio; and rating tools for evaluating information.

Suau and Masip (2014) designed a typology that would allow the creation of different models of media participation, choosing as starting point the concept of interactivity, which is divided into different types used to group the interactive features. Firstly, they define a group of features and services labelled "selective interactivity", which allows users to interact with the system in order to adapt the content according to their preferences and includes mechanisms for personalization. A second group of tools, under the term "participative interactivity", takes place in the context of a user-user or user-professional relationship and enables users to interact with journalists and other users. Parameters are previously established by the medium's website. Lastly, a third group of interactive features, labelled "productive interaction", also takes place in the context of a user-user or user-professional relationship and aims to contribution of original content.

Identifying the most prevalent and widespread participatory tools, Spyridou (2018) concluded to the following nine: i) Content rating, which is rating of content using the media organization's designated system, ii) polls, which are topical questions posed by journalists and answered by users using pre-determined responses, iii) sharing through social networks via buttons provided, iv) audience footage in

the form of audiovisual material, v) collaborative content (e.g. contributing interview questions), vi) comments regarding a news item, typically submitted through a form at the bottom of a webpage, vii) discussion forums, which are discussions led by journalists with topical questions posed by the newsroom in which submissions are fully or reactively moderated or places where readers can engage in threaded online conversations or debates, viii) submission of textual material and ix) citizen blogs, created by users and hosted within the news website.

Moreover, Spyridou (2018, p. 6) noticed that, although all dimensions are continuous and significant variability exists within each category, the aforementioned participatory tools can be split into categories of participatory activity. They range from very low, which enable little control, require minimal effort and are invited post hoc to high, which require most effort and allow for most control over content as planned and created before publication. Between them there is the category of low participatory activity, which also requires some effort, but enables more control than the first one over the published content, in the sense that it will either be published wholesale or not, again as a post hoc contribution and the category of medium participatory activity, which requires some effort and enables limited control over the content that will be published. Sharing is treated as a unique category, since, although it does not require substantial creative effort, it places professional work at a new, different to the initial, public space.

Problems and Quality Assurance Methods

The incorporation of UGC in the journalistic process is not an easy task, as the coexistence of professional and amateur content raises significant ethical, legal and responsibility issues (Saridou & Veglis, 2016, p. 88; Veglis, 2013). Concerns regarding UGC have been raised about the actual practice and its implications for culture, society and politics (Manosevitch, 2011). Some journalists see comments as a necessary evil which may attract audiences and help to the financial survival of the profession, but holds intolerable standards of expression (Singer et al., 2011). Moreover, there is the perception that comments frequently contain defamation, incitement, abusive content, racism or hate speech and thus the greatest challenge posed stems from their low quality (Singer et al., 2011, p. 103). Many also point to excessive use of inappropriate language, flouting, stereotyping and superficial discourse that impede constructive public discourse (Manosevitch, 2011, p. 425).

In the field of intellectual property, Deliyanni (2012, p. 324) classifies possible problems in three broader categories: Issues concerning the protection of blogs, profiles in social networking sites and websites along with the original content posted on them, issues caused by the violation of intellectual rights when creators' work is offered for free although made for commercial exploitation and issues of consolidation and reconstitution of intellectual works intended for commercial exploitation. Generally, journalists try to maintain high quality of spelling and grammar, to choose material suitable for publication and to ensure the balance and decency of the website (Thurman, 2008). Furthermore, responsibility issues become complicated as traditional legal liability models are questioned in the light of changing author, editor and publisher's role (Valcke & Lenaerts, 2010). When users produce content on a professional website, the debate on liability concerns not only them, but the journalist, the owner of the website and even the Internet service provider as well.

In order to avoid problems, media organizations have to manage participatory spaces, using methods of control on users' activity. Decisions on the practices employed by journalists are affected by several factors such as story topics, journalistic culture, newsrooms norms, perceived interest value and website traffic goals (Singer et al., 2011). When news organizations use pre-moderation, journalists try to assess every piece of UGC before published, following the logic of traditional participatory spaces; this prac-

tice offers a high level of security, but demands high financial, human and time resources (Singer et al., 2011). On the other hand, post moderation is a more open approach, comments are first published and professionals intervene if a reason occurs; such techniques are nearly always accompanied by mandatory prior registration and users have to submit personal information in order to be accredited as commenters (Singer et al., 2011, p. 109).

When distributed moderation is chosen, users are involved in the control process, often earning some kind of privileges (Lampe & Resnick, 2004). At the same time, some media organizations use technical methods that require less human intervention. Automated moderation, for example, is a purely technical method and UGC is accepted or rejected under predefined rules and filters that detect and replace banned words, phrases, IP addresses or whole paragraphs (Veglis, 2014), whilst Completely Automated Public Turing test to tell Computers and Humans Apart (CAPTCHA) is employed in the websites more rarely (Saridou & Veglis, 2016), aiming to block computer-derived mass entries. However, it appears that each strategy, whether autonomously or in combination with others, has an impact on how UGC is treated, not without financial and editorial stakes concerning cost, staff, time, quality and legality.

SOLUTIONS AND RECOMMENDATIONS

Apart from UGC that is produced on websites of media organizations, users also create content on social media platforms, extending news gathering process outside traditional spaces. Journalists use social media to look for breaking news events, find ideas for stories, keep in touch with their audience and gather information (Weaver & Willnat, 2016, p. 853). At the same time, however, digital content can be processed, intentionally altered or falsified and redistributed relatively easy, posing threats to mass communication and journalistic processes that can be associated to unwanted content tampering, construction of fake evidences, sharing and propagation of untrue stories (Katsaounidou & Dimoulas, 2018).

In order to exploit and verify UGC, media organizations utilize tools and platforms which enable them to obtain, sort and disseminate news (Katsaounidou, Dimoulas, & Veglis, 2018). Except for traditional methods, part of the collection, management and validation methods is sometimes based on semantic web services. However, such methods are not widely adopted by professionals and the need to trace in short time huge amounts of information coming from various sources remains crucial to the journalistic workflow (Saridou, Panagiotidis, Tsipas, & Veglis, 2018).

It is therefore important to design services which would aim at UGC exploitation, both of this submitted to media websites and of this created at social media platforms. It should be based on fully- or semi-automated methods, consisted of a content discovery procedure that would be followed by correction and moderation processes. At this point, a basic categorization would already have been developed and contributed to the initial handling of large-scale unstructured data. Afterwards, the most helpful step would be the implementation of semantic annotation tools aiming at effective management of UGC in order to prepare it for publication.

It is the role of journalist, however, that should define the structure and operation of the whole service. Although based on automation techniques, such an initiative should engage professionals not only at the stage of design, but also at the evaluation one. As news becomes more social, journalists have to develop their skills and use digital tools in the service of tracing information, forensic examination, UGC dissemination and verification (Johnston, 2016; Veglis, 2013). In order to verify content, professionals often use web-based platforms -like Truly Media (www.truly.media)- or tools developed in projects -like

Reveal (www.revealproject.eu)- which aim at finding and organizing information produced in social media and elsewhere. It thus seems inevitable that journalists' participation would enrich the procedure of designing a service for UGC management.

FUTURE RESEARCH DIRECTIONS

Future studies could focus on the stages of the creative procedure, starting from the model introduction and ending to the practical implementation of the designed UGC management service. Models that will be designed should effectively combine technical processes with professional norms, as at times of economic uncertainty, hyper-competition and diminishing accountability levels, convergence is used as a cost-effective strategy fostering low-cost and spreadable news production (Saridou, Spyridou, & Veglis, 2017).

Moreover, it is obvious that semantic Web tools can have an important impact upon how UGC may be treated by journalists. Semantic Web technologies, smart devices and tools are continuously being transformed and upgraded (Veglis & Bratsas, 2018) and so, in the future, journalists should be able to comprehend and utilize advanced technologies which will include more “intelligent web” (Bradshaw & Rohumaa, 2011). Research interest can thus focus on the way professionals are educated on the use of semantic technologies, while the study of their engagement in designing and developing UGC-focused tools can offer an insight on the integration of journalistic culture into technical procedures. In addition to this, their participation in the evaluation stage can improve the final product, especially in terms of usability and time saving. Notwithstanding the above, future studies should not neglect users' perceptions of involvement in news production in order to achieve accuracy.

CONCLUSION

This chapter examines the concept of participatory journalism, which evolves under technological and socio-economic developments, forcing media organizations to adjust their operation to the new challenges. Journalism websites offer a wide range of tools for UGC acquisition whereas at the same time huge amounts of information are created and shared by users on social media platforms. In such a context, a world of unstructured data calls for integration into the hectic pace of news production process. Hence, professionals try to incorporate UGC in their daily work routines not without facing possible threats to legitimacy and the established modus operandi, finding themselves in need of quality assurance methods.

At the same time, although semantic technologies can pave the way for the simplification of UGC exploitation, such practices are not largely spread apart from several heterogeneous tools and applications. Thus, the present chapter proposes the development of a service that will embody different functions –like content discovery, moderation and categorization- in a unique platform along with semantic annotation, which can contribute to content classification and verification. Journalists' education and subsequent engagement in design and evaluation of the service is considered to be of great importance for the success of the initiative.

KEY TERMS AND DEFINITIONS

Citizen Journalism: The form of journalism in which citizens hold the news production process without professional intervention.

Completely Automated Public Turing test to tell Computers and Humans Apart (CAPTCHA):

A test used to identify human Internet users in order to block computer-derived mass entries to a service.

Gatekeeping: The process of filtering information to decide whether it is suitable for becoming news and being disseminated.

Moderation: The process of checking UGC which is submitted to a media website.

Participatory Journalism: The form of journalism that takes place when content is co-created by journalists and users on an editorially controlled platform and when the content created by users elsewhere is then acquired and used by professional media outlets.

Registration: The process of submitting personal information in order to get access to participatory applications.

User-Generated Content (UGC): Online content in many types produced by users and made available for publication.

INTRODUCTION

The monolithic application of any process, disregarding the context conditions, may lead to unnecessary lack of effectiveness. By the contrary, the adaptation of any process to a particular situation is considered a good practice in many fields. Literature shows that this practice is quite common in Software Engineering processes, such as the methodologies Rational Method Composer (Haumer, 2005) and OPEN Process Framework (Firesmith & Henderson-Sellers, 2002). However, Requirements Engineering (RE) approaches are seldom tailored to context or project situations (Potts, 1995; Leite, Hadad, Doorn, & Kaplan, 2000; Leffingwell & Widrig, 2003; Seyff et al., 2009). Nevertheless, sometimes the elicitation activity, as part of an RE process, is performed taking into account some environmental characteristics, usually called situational factors, such as number of information sources, users geographical distribution, users time availability, users experience, among others (Maiden & Rugg, 1996; Hickey & Davis, 2003; Coulin, 2007; Carrizo, Dieste, & Juristo, 2008). Recently, some proposals have appeared to design an RE process for a specific project by selecting existent RE techniques (Lauesen, 2002; Lobo & Arthur, 2005; Alexander & Beus-Dukic, 2009).

There are activities of most of the requirements processes that are invariant regardless of situational factors, while others should be modified, removed or replaced. Not only activities may be adapted, models created in the process may be also suited for the situation (Galster, Weyns, Tofan, Michalik & Avgeriou, 2014). This means that these processes may be assembled like a flexible puzzle using interchangeable pieces depending on the situational factors identified.

Situational Method Engineering (SME) is advocated to build methods tailored to specific situations for the development of systems (Kumar & Welke, 1992). Following its principles, the adaptation of any software development process is based on indicators describing the situation (Khan, bin Mahrin & bt Chuprat, 2014). Part of the task is to compose such indicators based on observable factors, like degree of business processes reengineering, context complexity, developer expertise in the application domain, and project size, among others. Ideally, these situational factors should be considered before beginning the software process. However, there are factors not accurately known when initiating a software project, while other factors may change during the project. Hence, a dynamic view of the adaptation of a software

DOI: 10.4018/978-1-7998-3479-3.ch081

development process achieves a better performance of the process itself. Considering that defining requirements is the starting point of a software development, it should be necessary to pay more attention to factors influencing the RE process.

A frequent question of practitioners is related with the need of performing all the process steps to develop the software requirements. *Is it possible to shorten the road or to follow a different one?* Under some circumstances, there is an opportunity to reduce the RE process by deleting or simplifying activities; and sometimes different paths may be followed by choosing other techniques or even extending some activities. Project managers should make decisions depending mainly on the reality he or she is facing.

Therefore, the rational and some practice on the tailoring of an RE process according to a particular set of situational factors is presented in this chapter. Recommendations about the estimation of these factors are exposed as an enhanced solution. Additionally, some lessons learned, and future works are reported.

BACKGROUND

To follow a process guiding the development of an engineering project or system is valuable enough since it means that performing a predictable set of activities using techniques helps to get the outcome within a controllable quality.

Hence, the way the work is performed does not depend on individual criteria, allowing repeatability of costs, times and quality, and promoting the accumulation of knowledge about the process. The first activity of a process to develop a product consists in defining, as precisely as desirable, the expected outcome. When the product is a software system, this initial activity is an RE process, whose outcome is a consistent set of requirements. The RE process is particularly different from other activities of the software development process since it is the one that most interacts with people and their environment, while other activities are mainly carried out within the development team (Carrizo, 2009). Besides, project decisions impose constraints, tools and methods to carry out those activities. Therefore, if the requirements process takes into account the particularities surrounding the application context and the project itself, then it will probably result both in a better set of requirements and in a more efficient process.

Furthermore, a requirements process needs appropriate and continuous communication to gain as much customers and users compromise as possible. A better communication is achieved when all stakeholders use the same language. In RE, a proven way to accomplish this is by using the vocabulary of the application context (Leite, Doorn, Kaplan, Hadad, & Rida, 2004). Communication occurs when stakeholders orally interact, also when reports, documents and models are exhibited to customers. In this sense, natural language (NL) models, such as glossaries, use cases and scenarios, stimulate stakeholders' communication (Leite et al., 2004), and they are the most frequently used in RE (Kaindl, 2000; Leffingwell & Widrig, 2003; Seyff et al., 2009; Jacobson, Spence, & Bittner, 2011; Antonelli, Rossi, Leite, & Oliveros, 2012).

Software development processes put into practice in real projects are often forced to be adjusted due to contingent circumstances, sometimes in a poorly controlled fashion while the projects are ongoing. Hence, the situations within their application context and projects should be observed as the processes go forward for better tailoring to such evolution. Possible adjustments to the processes can be known in advance based on certain characteristics, though they may change dynamically, i.e., settings are pre-planned but only implemented when an aspect of the situation changes (Rolland, 2008). In this regard, the process may be defined as a set of blocks, having process blocks common to all situations and variant process blocks according to situational factors. Thus, the process is made up by assembling blocks for

the particular situation (Henderson-Sellers & Ralyté, 2010). Method Engineering has emerged to tackle this case, promoting the design, construction and adaptation of methods, techniques and tools in order to develop information systems (Brinkkemper, 1996). This discipline considers not only the creation of process blocks but also product blocks, and even blocks that assemble both process and product (Rolland, 2008; Henderson-Sellers & Ralyté, 2010; Ralyté, 2013). Rolland (2008) not only has pointed out that the software development should begin with a definition phase of the method to be used, but also she proposes that the process must be re-adjusted throughout its life cycle, an aspect not treated by Method Engineering. SME, as a sub-area of Method Engineering, focuses on building methods for software development, tailored to specific situations (Kumar & Welke, 1992). Thus, SME studies the factors affecting the software project and the application context (Bucher, Klesse, Kurpjuweit, & Winter, 2007). Its principles have been applied in RE to define requirements processes that are adaptable to particular circumstances by using existent modular components (Firesmith, 2004; Jafarinezhad & Ramsin, 2012; Bakhat, Sarwar, Motla, & Akhtar, 2015). These works can be grouped as follows:

- Group A:** Works oriented to define an RE process using frameworks. A knowledge base on RE activities and techniques is made available, serving as a guide to obtain an RE process according to the project's needs (Olsson, Doerr, Koenig & Ehresmann, 2005; Zowghi, Firesmith, & Henderson-Sellers, 2005; Jiang & Eberlein, 2008).
- Group B:** Approaches to select elicitation techniques that best suit to the situational context. These works only focus on the elicitation activity in the RE process (Hickey & Davis, 2004; Carrizo, Dieste, & Juristo, 2008; Al-Zawahreh & Almakadmeh, 2015).
- Group C:** Models that allow the RE process to be adapted when it is applied to a specific class of project. These are proposals of situational adaptation for projects of a certain nature or scope, such as global software development or agile methods (Bakhat, Sarwar, Motla, & Akhta, 2015; Abdullah & Khan, 2015; Kabaale & Mayoka Kituyi, 2015; Khan, bin Mahrin, & Mali, 2016).
- Group D:** Guides that facilitate the creation of an RE process adapted to the context. These works provide mechanisms for the creation of an RE process adjusted to the situational characteristics of the environment, within projects of any nature (Lobo & Arthur, 2005; Alexander & Beus-Dukic, 2009; Coulin, Zowghi, & Sahraoui, 2006; Jafarinezhad, & Ramsin, 2012), in contrast to works of Group C.

These works use notions of SME in different degrees of adherence to its principles, and they propose some factors to be evaluated in order to define the situation. Particularly, approaches in Groups A and D use process components to conform the new RE process. However, only proposals in Group D combine the concepts of SME with some principles of process variability.

The work presented by Hickey & Davis (2004), within Group B, poses a partially dynamic approach, an aspect that in general terms is not taken into account in other proposals. The authors emphasize that knowledge about the problem domain and the project domain is acquired as the RE process progresses, and thus, more appropriate elicitation techniques can be selected in each iteration. In addition, they mention that the situational characteristics of the problem context are usually static, while those related to the project may change, although they do not present evidence on the matter. In this sense, reminding what Rolland (2008) points out, contingent factors change during project life cycle, leading to a dynamic adaptation of the process.

Most of the studies related to the SME do not address two essential aspects: the incorrect adaptation of the process, and the probability of evolution or incorrect estimation of the factors that guide the adaptation. The first issue can occur under three variants: i) the inappropriate omission of doing an activity

that could be necessary, ii) the incorrect replacement of an activity by another, or iii) the unnecessary insertion of an activity. It is clear that the process adaptation is strongly dependent on the factors estimation, so a study of the evolution and estimation of situational factors can reveal issues not so easily visible, which can lead to an unsuccessful adaptation.

The work presented in this chapter is part of Group D. It aims to establish clear mechanisms to adapt an RE process according to particular characteristics of the application context and the project context, and to context evolution, considering that evolution may come not only from a real change of the situation but also from a better understanding of that situation.

Some of the adaptation factors are related to development time constraints. Naturally, they lead to faster ways of developing software; these are steps toward agile methods (Pineiro, 2002). A quality factor may depend on a time factor, or the other way around. However, a balance equation for both factors may be frequently achieved (Kohler & Paech, 2002; Pineiro, 2002). This trade-off is more likely to be better faced by an RE process with the necessary tailoring (Kohler & Paech, 2002). Extremely, when time factor is a major concern, agile methods could be the best way. Though, agile practices are frequently assumed as opposite to RE practices (Cockburn, 2002; Beck, 2004), Kovitz (2002) remarks that both, a phased development and an agile one, do RE but in different styles, since requirements are always present. This vision is also shared by (Sillitti & Succi, 2005; Kohler & Paech, 2002). In this sense, an agile approach dealing with requirements may be also seen as a sort of dynamic adaptation of an RE process. As Cockburn (2002) said, making the decision on the right level of agility is the best way to succeed on a project. RE practices do not deny agility, considering that this property must be combined with quality and attending volatility without constant software fix (Pineiro, 2002).

AN ADAPTABLE REQUIREMENTS ENGINEERING PROCESS

Tailoring a Requirements Base Process

RE process based on NL models strongly contributes to stakeholders' commitment to the project. As a standard or base process, it involves the following stages:

- **Identifying the general software goal and scope.**
- **Understanding the vocabulary used in the application context**, supported by the Language Extended Lexicon model (Hadad, Doorn, & Kaplan, 2009).
- **Understanding the application context**, supported by a set of current scenarios that represent the situations observed in the application context (Leite et al., 2000).
- **Refining the general software goal**, by decomposing it into sub-goals.
- **Defining the software context**, by producing a set of future scenarios that represent situations envisioned in a future application context where the software system will operate (Leite et al., 2004).
- **Defining the vocabulary used in software descriptions**, by producing a Language Extended Lexicon of the System (LEL-S) created from the previous one, adding terms used in the descriptions of future scenarios.
- **Making explicit the requirements**, by producing consistent requirement specs, after extracting requirements from future scenarios. Eventually, a Software Requirements Specification (SRS) document may be produced.

This RE process has been initially developed, tested and used in a monolithic fashion, as depicted in Figure 1(a), ignoring all special circumstances. Actually, this implies a somehow poorly defined standard context. It should be noticed that the base process in Figure 1(a) is decomposed in sub-processes, where most of them are composed of another level of processes, as shown in Figure 1(b). Recycles in the two diagrams of Figure 1 were removed to emphasize the variation points, which are introduced here only for the proposed adaptation solution. These recycles imply correcting or updating models because of a better understanding of the problem and of the evolution of the application context.

Figure 1. Requirements Engineering Base Process, expanding one main sub-process

Though Figure 1(a) shows a monolithic process as part of a waterfall model, the strategy can be adapted to be used within different software process models, being this a project factor by itself (see Table 1). For instance, when following an iterative or incremental process model, all sub-processes (except the first one) are done in iterations along with a requirements change management activity throughout the software development life cycle. In case of developing an incremental RE process, the increments may involve the enhancement of previous functionalities and properties, or the addition of new ones; this is treated by a specific factor, which may take different values in each cycle. Regarding agile practices, additionally to time constraints, another leading factor is volatility (Cockburn, 2002), which may be well

coped with a change management activity. However, it may not be the best manner when volatility is a core characteristic of the context. Therefore, an agile method might be a better proposal to satisfy customers.

This RE base process may be adapted at the variation points shown in Figure 1(a), depending on a combination of situational factors. Project managers should do the adaptation to improve the RE process and, thereby, the requirements product. Situational factors impacting on RE (see Table 1) have been selected based on experience in RE practice and literature proposals (Maiden & Rugg, 1996; Hickey & Davis, 2003; Carrizo et al., 2008; Ebling, Audy, & Prikladnicki, 2009; Jafarinezhad & Ramsin, 2012; Mighetti & Hadad, 2016). These factors can be characterized by the following attributes:

- **Value:** Admissible values depend on each factor
- **Confidence on the value:** Sure, Reasonably Sure or Doubtful
- **Origin:** Application Context or Project
- **Evolution type:** Invariant or Contingent
- **Variation points:** Where the factor impacts on

In order to adapt the RE process, project managers (or method engineers) assign values to factors, qualifying them with their degree of confidence on such values. It usually happens that at the very beginning some factors may be not precisely known, and right values are known after gaining a better understanding of the situation. Factors are classified according to their origin into those related to the specific application context, and those related to the specific software project. From an evolution dimension, factors are classified into: *Invariant*, being those that do not change during the RE process; and *Contingent*, being those that may naturally evolve due to changes in the application context and/or in the project context.

Interaction among factors should be taking into account when tailoring the RE process. *Neutral interaction* implies that two factors are fully independent, having no influence between them. *Overriding interaction* indicates that a factor is discarded when another factor takes a specific value. *Limiting interaction* points out that a factor may reduce the range of acceptable values of another factor. *Incompatible interaction* implies that the values of two or more factors cannot be accepted simultaneously at the same project; thereby, the value of at least one factor has to be changed through stakeholders' negotiation to solve the inconsistency. Examples of these interactions are:

- **Overriding interaction:** The factor Business Process Reengineering is not taken into account if the factor Novelty of the Context takes the value *Yes*.
- **Limiting interaction:** The factor Software Process Model cannot take the value *Waterfall* if factor Context Volatility is *Very High*.
- **Incompatible interaction:** The factor Software Reliability is *Very High* while the factor Project Time and Resources Constraints is *Very Low*.

Each sub-process is defined by a sequence of process blocks, some of which include product models. At each variation point, a base process block may: i) stay as it is; ii) be deleted; iii) be replaced by another process block; or iv) be replaced by a process block with a partial internal variation based on parameters. Figure 2, exploiting sub-process of Figure 1(b), shows how the instance of a process should be constructed according to specific situational factors, using a repository containing all possible atomic blocks. This Figure exemplifies one process block (*Deriving Current Scenarios*) that may be replaced by one of three different atomic processes and, by the way, all process blocks are parameterized.

Table 1. Situational Factors impacting on RE process. Range Very High to Very Low includes five possible values

Context Factors	Acceptable Values	Type of Evolution
Context Complexity	Very High to Very Low	Invariant
Target Customer	Taylor-made, Market-driven	Invariant
Novelty of the Context	Yes, No	Invariant
Business Process Reengineering	Very High to Very Low	Contingent
Context Volatility	Very High to Very Low	Invariant
Volatility of Users Needs	Very High to Very Low	Invariant
Inconsistencies in the Context	Very High to Very Low	Invariant
Conflict among Users Interests	Very High to Very Low	Contingent
Users Rotation	Very High to Very Low	Invariant
Users Location	Co-located, Distributed	Invariant
Project Factors	Acceptable Values	Type of Evolution
Familiarity with the Domain	Very High to Very Low	Invariant
Project Size	Very High to Very Low	Contingent
Developers Rotation	Very High to Very Low	Invariant
Software Reliability	Very High to Very Low	Invariant
Reuse of Existing Requirements Artifacts	LEL, Current Scenarios, Future Scenarios, LEL-S, Requirements, No	Invariant
Demand to Create Requirements Artifacts for Reuse	LEL, Current Scenarios, LEL-S, Requirements, No	Contingent
Demand of Requirements Pre-Traceability	Total, Partial, No	Invariant
Demand of Requirements Post-Traceability	Yes, No	Invariant
Granularity of Requirements Traceability	Individual, Group	Invariant
Demand to Produce an SRS	Yes, No	Invariant
Project Time and Resources Constraints	Very High to Very Low	Contingent
Software Process Model	Waterfall, Incremental, Iterative, Formal Transformation, Other	Invariant
Type of Software Increment	New Functionality, Enhanced Functionality	Contingent
Experience in RE Process	Very High to Very Low	Invariant
Cultural and Language Barriers	Very High to Very Low	Invariant
Time Differences among Stakeholders	Very High to Very Low	Invariant

There are common elements among the various parts of the RE process. For example, Figure 2 shows three process blocks *Scenarios Derivation*, *Scenarios Organization* and *Scenarios Verification* which are shared with another main sub-process *Future Scenarios Construction*. There are four types of atomic process blocks. An *own block* is that not shared by any other main sub-process and is independent of situational factors. A *shared block* is common to different sub-processes of the RE process and may depend on factors. A *variant block* belongs to a specific sub-process and depends on situational factors. A *null block* is an auxiliary block used when an entire sub-process or an atomic process must be deleted or skipped from the basic RE process. Table 2 shows operations that may be applied to each type of process block.

Figure 2. Defining the Current Scenarios Construction Sub-Process

Table 2. Valid Operations on Basic Process Blocks

BLOCK TYPE	OPERATION			
	Stay	Delete	Replace	Parameterize
Own	✓	✓		✓
Shared	✓	✓		✓
Variant		✓	✓	

Some process blocks include product models, which contain minor variations of the NL models produced by the RE process. For example, if the lexicon model is not created, then the scenario model does not include hyperlinks to lexicon symbols.

Meta-Process for a Dynamic Adaptation of a Requirements Process

The adaptation of the RE base process involves a mechanism of operations on process blocks at every variation point, using a specific combination of situational factors, following SME principles. The variation points are milestones used to review the RE process and to indicate possible re-designs of remaining RE activities. The way of constructing the RE process for a specific situation includes the following activities (see Figure 3):

1. **Factors Set-up:** The situational factors are evaluated, assigning a degree of confidence to each value, taking into account the interaction among factors. A simple form is used to collect the factors value. This form eases its filling with valid values by means of rules for factors interaction.
2. **Factors Analysis:** The factors setting is analyzed considering mainly interactions and factors with low confidence. Project managers should take a position on every factor with low confidence: optimistic, conservative or balanced position. Under an optimistic position, factors are assigned an

- extreme value of its valid range depending on the meaning of the factor, while under a conservative position factors take the opposite extreme value. A balanced position involves choosing intermediate values. This re-allocation of values is done to allow assembling the process, since the original values are preserved. When incompatible interactions are observed, a negotiation must take place.
3. **Factors Negotiation:** The purpose of this activity is to reach an agreement among stakeholders by modifying the causes that bring out the incompatibility. Then a re-assignment of values to one or more of the involved factors is done. After negotiation, a partial analysis of these factors takes place.
 4. **RE Process Assembly:** The RE process is assembled departing from the base process, considering a subset of situational factors at each variation point. A set of rules based on a specific combination of those involved factors defines which operation is applied over each base process block (see an example at Figure 2, right part). Thus, this assembly activity consists in maintaining, deleting, replacing, or parameterizing process blocks.
 5. **Factors Re-Evaluation:** At every variation point, those factors involved in remaining variation points must be re-evaluated. Low-confidence factors must be watched, since its level of confidence is supposed to increase due to a better perception of the situation. Contingent factors must be also watched to establish if a change in the situation has occurred. After this activity, a new factors analysis is needed in order to ensure the absence of inconsistencies among dependent factors.

Figure 3. Process for Dynamically Tailoring an RE Process, based on situational factors

Issues on Situational Factors Evaluation

The evolution of 21 situational factors has been studied during the developing of the RE Process in 35 industry projects. This study has allowed corroborating the evolution of the situations and, addition-

ally, to identify factors to which more attention must be paid for a suitable dynamic adaptation of the requirements process.

This study had confirmed some underlined initial hypothesis, such as:

- The confidence increased along the Requirements Engineering process: the initial percentage of doubtful factors was 12.8 and near to the ending, this figure was 4.7.
- The confidence on the context factors is higher than the confidence on the project factors: the initial percentages of doubtful factors were 7.2 and 17.0 respectively, while near o the ending they were 3.0 and 5.9.
- High level of variation along the project occurred in some presumed contingent factors. Most relevant variations were on factors: Business Process Reengineering with 54% of changes and Project Size with a variation of 46%.

However, some unexpected observations also occurred:

- There are still doubts on the value of some factors when the RE process was almost finishing, with a notorious 12% of Demand of Requirements Post-Traceability, 10% on Volatility of Users Needs and 9% on Project Size.
- The overall percentage of factors with relevant change was of 33.2, which is higher than expected; 86,5% of them were obtained with high degree of confidence. These does not discard estimation errors.
- High level of variation along the project occurred in some presumed invariant factors. Most relevant were Software Reliability with 53% of changes with an 87% of no doubtful estimation, and Demand of Requirments Pre-Traceability with 44% of changes in a context of 20% of doubts in the estimation.

SOLUTIONS AND RECOMMENDATIONS

Since selecting the appropriate RE process for a specific situation is crucial, project managers should define as precisely as possible the situational factors in order to construct a suitable RE process. However, they should be aware of the potential evolution of the situation and, thereby, review factors and adjust the RE process at pre-defined milestones.

Evolution of the situation is a key matter that must not be underestimated. Factors may naturally change due to context evolution, or some may require an update due to unprecise prior estimations. Therefore, the quality of estimating situational factors is critical for a satisfactory RE process adaptation.

The analysis of the results of the factors evaluation study lead to recognize that a good quality estimation may be not so easy to do at early stages

Factors estimation requires new evaluations while performing the RE process adaptation. This activity must be mainly focus on those most unpredictable factors (contingent factors), and on those whose values are more difficult to perceive. Furthermore, when reevaluation takes place, it should to be taken into consideration that changes in some factors may impact changes over others, and these changes should not be incompatible with the part of the RE process done before.

The factors evolution study has revealed that uncertain or incorrect factors estimations are mainly due to lack of or poor guides for developing the RE activities and, somehow, due to a poor factors definition.

FUTURE RESEARCH DIRECTIONS

Feasible variants of the process were identified due to the experience achieved after putting into practice the RE base process in many software projects in industry along more than two decades.

Situational factors were exhaustively studied in literature, although this set is likely to be extended. A first extension was made since the previous work published in (Hadad, Doorn & Ledesma, 2018). Factors affecting subsequent phases of the software development process will be studied to determine if they may influence backward on the RE process.

The decomposition of the RE process in base process blocks, along with the set of situational factors, has allowed identifying process commonality and process variability, and hence defining the different types of process blocks needed. It is planned to evaluate the convenience of using mixed blocks, or separated process blocks from model blocks. It is also considered that more cases should be done to confirm the different branches of the adaptable RE process.

New studies focusing on the weakness already detected on factors estimation will be carried out.

CONCLUSION

The proposal presented in this chapter deals with variability in an RE process, driven by a dynamic adaptation based on prevailing situational factors.

Most problems have distinctive features that must be taken into account to carry out a successful requirements process. Project managers should tailor the requirements process by choosing the techniques that are most suitable for specific situations. When guidelines on how to adapt the requirements process are provided, managers are more willingly to do it.

The meta-process for constructing an RE process involves a set of factors that typifies situations considering both the application context and the software project context. This adaptation process establishes when the RE process should be reviewed and re-tailored based on rules and operations at each variation point. Since it is frequently observed the natural and contingent evolution of situations, it is important to have the possibility of redefining the remaining activities of the RE process once the project is in course. Focus should be put on the possibility of an incorrect evaluation of certain factors, being aware of the necessity of re-adaptations to avoid a bias towards an unsuccessful process.

The adaptation of the requirements process for several real cases has contributed to its acceptance in host organizations. It is considered that the dynamic adaptation process could be implemented with minor adjustments in other RE strategies.

KEY TERMS AND DEFINITIONS

Natural Language Model: A model built using a minimum set of structural components and completed with slightly restricted natural language text.

Process Block: A well-defined unit of process that can be reused as part of any process.

Process Commonality: The common elements of a process that facilitate the definition of a family of processes through reuse.

Process Variability: The variant elements of a process, identified at variation points, which produce deviation from the standard process.

Requirements Engineering Process: A process to construct software requirements by means of methods, techniques and tools during elicitation, modeling, analyzing and evolution of requirements.

Scenario: A representation of an observed or envisioned situation in the application context.

Situational Factor: A characteristic of the project or the application context that may be taken into account when defining an RE process.

Situational Method Engineering: A discipline that promotes the construction of methods for developing systems according to a pre-defined set of situational factors.

Variation Point: Specific location at a process where situational factors are evaluated and changes to the standard process are applied.

Digital Tools Aimed to Represent Urban Survey

9

Cristina Boido*Politecnico di Torino, Italy***Pia Davico***Politecnico di Torino, Italy***Roberta Spallone***Politecnico di Torino, Italy*

INTRODUCTION

Since the affirmation, in the Sixties, of Urban Survey as a subject in the field of drawing's disciplines, it aimed to represent a set of three-dimensional data on a plane.

This aim emerged in the European researches carried out by Pierre Lavedan and Augusto Cavallari Murat that triggered a discussion about the values characterizing the historic city, in particular the Baroque one, and the ways in which these values could be represented. Cavallari Murat and Lavedan shared that the values of the Baroque city could be represented through a concise drawing, as had happened in some famous maps of the past, in particular, that of Rome, drawn by Giovanni Battista Nolli.

In 1968, Cavallari Murat and his group of scholars published the books *Forma urbana e architettura nella Torino barocca* (Politecnico di Torino, Istituto di Architettura Tecnica, 1968), in three volumes.

The urban survey maps of Baroque Turin, drafted in scale 1: 1000, made up the third volume. They are based on the tables of the geometrical particle cadastre, drawn in 1823 by Andrea and Alberto Gatti, and on the municipal map of the time. The urban survey maps represented a selection of data collected through archival research on iconographic documents and texts, such as censuses, and aimed to become a knowledge basis for preservation and intervention on Cultural Heritage.

The morphological, typological, and stylistic data, were collected in a drawing of the ground floor, where the public spaces were distinguished to the private ones. The goal was to provide, through a map, a series of information about the three-dimensional feature of the historic urban tissue, using the so called stereometric symbols, that represented: the upper cornices, the number of storeys of the different building units, the virtual projection of vaulted and beamed coverings, the openings' axes of the main floor, the stairs as elements of vertical distribution, and the entrances to the housing units in the standard floor.

In 1974, Cavallari Murat proposed symbols for the survey of historic urban tissues, stated in the 1968's research, within the standard UNI 7310-74 - Urban Cartography. Graphic Standards, for representing historical urban tissue, mainly characterized by multi-storey buildings.

This methodology of urban survey representation can be broadened to urban tissues, not necessarily characterized by historical values.

The authors of this paper worked in the research group directed by Dino Coppo, a pupil of Cavallari Murat and are today involved in researches about the potentialities of digital tool for representing urban survey.

DOI: 10.4018/978-1-7998-3479-3.ch082

Figure 1. Philological conjectural survey of Baroque Turin. Source: Politecnico di Torino, 1968.

Indeed, digital revolution allows to represent urban tissues by 3D models that can collect a lot of information related to the buildings, becoming real data base.

Today, these models fulfil the need for update representations of urban settings, aimed both to critical studies on historical city and to manage the ongoing transformations. Moreover, these representations could become the urban scenarios for simulations and checks of master plans and architectural designs in their relationships with the built environment.

Several new tools of urban procedural modelling, BIM modelling and web resources allow generating urban 3D models.

The authors of this paper will compare the knowledge and informative capabilities of different new technologies for urban modelling, through an overview of international researches, case studies, and also some experiences personally carried out.

BACKGROUND

The representation of the environment, the city, a building, and the different aspects that define them, in an articulate relationship between tangible and intangible elements, has always been a complex matter, due to the difficulty in “narrating” and using images to summarise the various closely related aspects that make them what they are. Digital modelling combined with the latest information technology has made a fundamental contribution to creating new and constantly evolving communication scenarios which offering such a wide range of potential means and ways of representing the city as to require very careful design of the process used for the selection and communication of information.

If today’s new multimedia tools allow an immediate and interactive communication, often addressing a wide range of users, when studying a given urban or environmental reality, it is necessary to identify

forms of representation that are capable of easily and immediately transmitting urban situations and processes that can be complex, generally characterised by articulate relationships between multiple aspects, of which form or appearance are just two. The study of the city, of its being a combination of tangible and intangible elements and situations linked to its past as well as its present and even its future, configurable through images or movements generated by fruition-functional dynamics, is a study linked not only to established Urban Survey practices (Coppo & Boido, 2010) but one that is increasingly interdisciplinary, and is the basis for each representation or digital modelling, as a tool for knowledge and divulgation.

With the spread and enhancement of information technology, in recent years there have been profound changes in the access to and management of information, in spatial analysis and in graphic rendering methods. Since the 1980s, the development of GIS systems has led to formidable innovations, offering the possibility to create increasingly advanced models, using mainly data from satellite sources. The improvement in information technologies has favoured the expansion of the methods of collection, management and processing of geographical data, configuring the possibility of integrating different types of graphic rendering.

Moreover, thanks to fast and simple 3D navigation via browser and to the simplified interface of webGIS viewers, urban scale three-dimensional representations, deriving from the countless quantities of information available today, in terms of quantity, quality and variety, are considerably enhanced and widely available. The three-dimensional images of space, particularly urban space, perfected by virtual reality technologies that allow an increasingly realistic view of the environment, allow the exponential strengthening of the communicative capacity of these representations. No longer intended only for technicians working in the field but also easily understood by the general public, they allow infinite, or almost infinite, possibilities of reading, adapting to each specific need, to the point where they are almost customized. An example of this is Google Building Maker, a web application that was created in 2009, in which digital modelling was aimed at engaging the general public, allowing the individual user to play an active role in the construction of the three-dimensional image of a building to be included in Google Earth. The tool allowed the incorporation of a 3D vector representation, built with Google SketchUp modelling software, with two-dimensional raster photographs, generating scenarios suitable for depicting environmental and building features, as well as the inclusion of urban interventions. Photographs of the facades provided by the program were applied by the users on geometric 3D buildings modelled by them, and then the models were validated for inclusion in Google Earth.

This kind of representation merged 3D geometric model and photos that are products ontologically different in many respects.

Indeed, the model is a three-dimensional vectorial entity, whose faces are mostly plans, while the photos, applied on it, are two-dimensional raster entities that represent different planes projected from a point at a finite distance analogous to that perspective.

However, despite this operation was unacceptable from the science of representation point of view, it had the advantage of generating scenarios freely available for the insertion of planning and designing proposals.

The photos applied on models allowed the users to appreciate a good degree of realism of architectural morphologies and decorative styles of the context, in relation to the architectural shapes of new projects and masterplans. Furthermore, the possibility for the user to move around in a virtual reality in real-time 3D, generated a kind of dynamic photo-montage.

This method for generating urban and environmental contexts quickly became obsolete, also due to some inconsistency between the models realized by different users, and was withdrawn by Google in 2012 (Lo Turco & Spallone, 2013).

From 2017, Google Earth offers the biggest repository of photorealistic digital version of the planet. The imagery was collected by satellites (for global 2D images) and planes (for more detailed 3D data near the ground). The photos are taken from five cameras having different angulations and need to be overlapped. After preparing the photos and calibrating the colors, a depth map is created. The different maps are stitched together and a 3D mesh is realized. Finally, 3D mesh is textured with the photographs taken, producing a really photorealistic imagery.

The above described different kinds of models, used for urban analysis and planning, but also in the field of architectural design, are used as a basic support for the design of the city and its context.

Now necessary not only to represent individual situations (energy analysis, traffic, pollution, etc.), but, using specific parametric software, they become essential tools for analysis, design and visualization for city planning.

In 3D maps and models there are always more and more apps and other tools that support information and communication technologies, also in real time, with quality and accuracy. Among many, it is an example Simplex 3D models.

These applications are useful for civic innovation and development, from conception to action by combining analysis tools.

MAIN FOCUS OF THE ARTICLE

Overview

While digital modelling was used in the past to create 2D and 3D images which represented a shape or synthesized non-interactive studies on the city, today, with its use on several fronts, it has to be diachronic and questionable. It must be able to represent both present and past (just think of the reconstructions of ancient cities that have disappeared or of which only faint traces remain), and even the future (conceived, designed) to which it is possible to convey shape and attribute an image, with the possibility of adding new ideas for urban transformations (on every scale, from territorial to architectural or in detail) within the context in which they are to be proposed. This whole process requires Urban Survey methodologies and practices to work on different fronts, simultaneously considering measurable data and the elements of perceived reality (visible and not only), in an activity which, especially in its possible applications also in the design field, requires necessarily the involvement of multiple disciplinary contributions, ranging from those in the morphological and socio-economic spheres to government policies. In this scenario, which is extremely wide due to the variety of possible uses and communicative instruments that can be used, digital representation and its dissemination must be structured and designed in relation to the purposes of their use, adopting different and adequately calibrated paths of study and expression in each individual case, taking on a primary role in all kinds of communication, which can also be interactive.

Digital modelling must therefore aim to prefigure urban scenarios using different methodologies, capable of externalising the various aspects that define and characterise each area, architecture or part thereof, basing the representation on geometric-topographic matrices, which are an essential reference for what currently exists and its possible future transformations or, on the contrary, on urban situations from the past (e.g.: the incredible models that now allow us to visualize the shape of lost cities and buildings) (Brusaporci, 2010).

In this broad study process, the starting point is unquestionably defined by the data collection and processing phase, by the selection and interpretation of said data and by the choice of how to represent

them in a digital model capable of visualising the different and increasingly interactive aspects. This is how, after this phase, the various disciplinary approaches involved in the activity converge in relating through a single model, realized increasingly through the interconnection between different tools and methods (such as metric acquisition tools, georeferenced databases and a myriad of other more or less well-known 3D modelling programmes available today, some of which available also in open source format).

For the reconstruction of complex scenarios, exploiting new technologies for dynamic and interactive 3D modelling has proved and is increasingly proving to be a very useful tool, especially during the analysis and programming of interventions on an architectural and/or urban scale. Examples of this are HBIM (Heritage Building Information Modelling) in the field of restoration and requalification of the existing historical heritage, and BIM, linked in particular to new design, both of which are fundamental aids for the processes of planning, transformation and development of cities or parts of them, where it is useful to verify in advance the various aspects, not only material. The integration of the various types of information in a single model simplifies the complexity of comparison, dialogue and conversation, also reducing timing, from those concerning the survey and design phases to those of approval, through to actual operation, streamlining and accelerating each process of urban transformation and its related costs.

These new communicative approaches, which are increasingly used to gain a critical knowledge of what already exists and for the upfront testing of the consequences of transformations (large-scale or localised), in cases already experienced have led (and are leading more and more) towards the integration of information between those involved in the intervention and future users, with benefits in several directions. An interactive digital model must, in fact, improve the visibility and understanding of each phase of the process, not only for professionals but also for those who feel involved, who want to play an active role, thus promoting the implementation of a “shared interactive project”.

The visualisation of the de facto state and/or transformations of any urban reality, whatever its size, allows us to clearly understand its multiple aspects, encouraging an immediate comparison between what already exists and design, and to follow the planned process of transformation from the conceptual phase to its possible tangible and intangible effects. This strength of this new methodological approach lies in the communicative simplicity of an interactive model, because the model itself becomes the point of encounter and comparison between the different subjects who interact in the survey and transformation process (Disegnare Con, 2018). This process is characterised by the transparency of information, because the “visibility” of the intervention phases creates trust in the community, building a dialogue between the principal, the professionals engaged in the work and the general public or interlocutors involved in discussions about the future framework outlined in the model.

International Case Studies

The most recent experiences have shown that by increasing clarity, comparison and control of possible impacts and effects in prior simulations, applicable to every kind of operation within the city, with specific digital models, it is possible to obtain benefits. These benefits derive mainly from the correction of the operations planned, before or during the implementation phase, using the model to test the entire planning and programming process, or rather the physical, functional, economic and strategic opportunities that could derive from it, up to the point of considering those of a change in the image or liveability of a place, more closely related to people. This type of programmatic and interactive working approach is being used increasingly, and not only for large cities, due to the benefits it brings.

The possibility to interact and interface by using interactive digital modelling has meant that there are no longer separate models, created for each field of interest or investigation, but a single working tool in which to visualise and describe different operations and skills, so much so that it can also be used by non-experts in the field.

A virtuous experience is undoubtedly that begun in 2009 by the municipal administration of Berlin (Senatsverwaltung für Stadtentwicklung und Senatsverwaltung für Wirtschaft, Energie und Betriebe). Using non-commercial programs, a three-dimensional model of the city was created, based on aerial photographs of 540,000 buildings located within an area of 890 square kilometres and laser measurement of their covers. In addition, photorealistic 3D urban restoration was implemented with architectural scale models of 80 buildings, considered to be emergencies in the urban building fabric, five of which can also be visited inside (Olympic Stadium, Sony Center, Reichstag, DZ-Bank, Ostkreuz and the Central Train Station). The goal was to map the city to allow people to look at Berlin from any angle, how it is now, how it used to be and how it might change in the future. Made for non-commercial purposes, the model offers the chance to visualise recent historical transformations as well as future urban development projects, using two-dimensional and three-dimensional geodata. Using two platforms characterised by different contents and applications, *Economic Atlas Berlin* and *Berlin 3D - Downloadportal*, it is possible to take three-dimensional urban walks, consult detailed maps, view 3D buildings and retrieve specific information on the urban area of Berlin, highlighting infrastructures and public services (public transport, schools, kindergartens, scientific institutions, etc..). It is also possible to consult information on all public and private commercial properties available on the Berlin real estate market, both for those who intend to invest and for those who offer investment opportunities, directly experimenting with hypothetical scenarios of urban transformation visualised in 3D. Again, the 3D model proved to be extremely useful for visualising the city's solar potential right down to the individual building. Supported by Solar Atlas Berlin, an online atlas for calculating the potential energy yield, graphic rendering during the design phase enables verification of the suitability, adequacy and actual efficiency of a solar system to be installed on the roof of one of the city's many buildings. Flexible and versatile in adapting to different visualisations, this virtual animation of urban and partly architectural realities is one of the most interesting current representations of the city (Berlin Business Location Center, 3D City Model, 2018).

Figure 2. Berlin 3D City Model. Source: Movie by Berlin Business Location Center, from 2009

Another example related to urban scale modelling for energy verification purposes is the SeNECA project, developed as of 2015 (SeNECA - Smart and sustainABLE City from Above, 2018). It can be considered a prototype web portal capable of showing 3D visualisations of the building fabric, with a view to verifying and improving the energy efficiency of the existing building heritage, developed for the cities of Trento and Graz. Using aerial images, photogrammetrically processed to produce ortho-photos and precise three-dimensional models, compared with cadastral data and information on energy consumption and requirements, the tool offers the chance to identify where to operate to reduce urban energy consumption. The models, accessible via the web as a common basis for representing urban and energy data, and for reporting heterogeneous information and planning urbanistic and energy efficiency activities, can be consulted through mobile platforms thanks to the use of Open Source technologies.

Looking more generally at what has been achieved in recent years, with regard to urban areas we can identify models on some recurring themes, which have a greater impact on existing and future scenarios. For larger-scale modelling of cities and the territory, there are many examples of infrastructural transformations for mobility. Actually, digital models visualise the movements of the entire network, allowing us to understand the public transport service coverage of the territory, verify movements, timing, costs and the impact on the environmental image, through the construction of infrastructure (tracks, underground railways, stations, etc ...). The model, in cases that have already been tested, such as the visual communication programme “Sydney Trains”, has been a reference to help people understand, criticise, accept or reject the changes envisaged by the project, allowing corrective measures before the implementation phase (Sydney Trains – Visual Communications Program).

In other cases, such as City of Gold Coast in Queensland (2014), aimed at redesigning entire sectors of the city, the model was developed to visualise and verify the volumetric impact on the existing situation of design operations for the creation of new buildings, allowing us to understand how much, and in what way, their presence and their size would change the urban physiognomy, assessable in relation to different points of view (City of Gold Coast Draft City Plan, 2015).

Figure 3. Gold Coast, Queensland, 3D City Model. Source: Movie by City of Gold Coast Draft City Plan 2015 - Nobby to Surfers, 2015

These works often combine the study of volumes, the study of the exposure to sunshine that would occur by varying them, and the analysis of artificial lighting, to calculate and refine the lighting ratios between what already exists and the future configuration. This is carried out via visual simulation, allowing the simultaneous calculation of the energy impact resulting from the different configurations assumed, and the consequent identification of the best solutions, making it possible, using the model itself, to alter the volumes of new buildings that are planned in relation to the shadows that they would cast.

Digital modelling, with its dynamism, leads to the visualisation and understanding of scenarios of viability and architecture, linking what exists with what is proposed by the project, configuring any change that, with subtractions, additions or other variations, leads to a better understanding of every alteration, from large to small scale. An example is provided by cases concerning not only buildings but also the design of roads and links, allowing not only the visualisation of new solutions, but also the ability to interact, changing their directions, curvature, etc..., also during business meetings (sometimes in video conference), in which technicians intervene on the model, changing some elements “live”, to verify, for example, the improvement of flows or the organisation of connections with other parts of the city or territory.

Figure 4. Examples of interactive use of the 3D model. Source: Movie by Urban Circus 2017, 2017

An interesting case in which this way of working has recently been used, through the creation of a single interactive model, is that tested by the city of Melbourne. This example allows us to understand the usefulness of a single work support, which facilitates coordination between all those involved in the complex succession of phases concerning interventions on the city or on the individual building, closely related to each other.

Figure 5. Flinders Street Station, Melbourne 3D City Model. Source: Movie by Urban Circus Projects

This working method is very often used in the architectural field, for single or integrated design, in which modelling through analytical steps can define and configure every aspect of the project. The model allows us, through the visualisation of the architectural aspects, to understand the configuration of the new intervention and to know the relationship with the urban context, on different levels of observation. This approach, which is also increasingly used to propose ideas for transformation to various scales of interest related to each other, is exemplified in the competition for the redevelopment of Victoria Station in Melbourne, won in 2013. The model is used to display various scenarios related to the stages of implementation, envisaging not only aspects of form and technological-constructive aspects, but also those related to timing or costs, with the possibility of continuous updating.

An Experimental Research

A case study carried out by the authors' School applied BIM technology to a diachronic and multi-scalar management of digital models, aimed to represent an urban survey.

Indeed, BIM potentialities have been tested in an innovative way on the case study of a medieval settlement of particular morphology Montemagno in Asti territory (North-West Italy). It is featured by a comb-shaped layout interspersed by narrow alleys, placed on a system of three ridges. This research involved analyses at the urban, micro-urban and architectural levels, carried out by historical, bibliographic and archival research, cartographic surveys and measurements in situ. A BIM synthesis model allowed to appreciate, at different scales, the historical transformations, read with the regressive method, up to the application of stratigraphic analysis methodologies on the facade's surface of an exemplar building, the Accornero house.

Figure 6. Periodization of Montemagno (Asti) historic settlement development. In light gray the existing buildings, in dark gray the new constructions. Source: (Spallone, Piano & Piano, 2016)

The research used tools whose applications to historical buildings is currently object of study by scholars in the field of HBIM. Compared to existing studies, however, this approach used some functionality for the control of the time dimension not yet properly explored, interlacing with the archaeology of the elevations and the stratigraphic Harris Diagram (Matrix), in order to facilitate the analysis.

Figure 7. Orthophotos and Harris Diagram applied to Alley V in Montemagno. Source: (Spallone, Piano & Piano, 2016)

The case study was developed by Andrea Piano and Simona Piano as part of their Master's thesis in Architecture Construction and City, at the Politecnico di Torino, under the guide, as supervisors, of Roberta Spallone and Carlo Tosco. The interdisciplinary approach, now more than ever necessary in the investigation on Cultural Heritages characterized by a high level of complexity, such as urban and

architectural ones, thus involved the disciplines of Urban Survey, Representation and History of Medieval Architecture (Spallone, Piano & Piano, 2016).

The range of applications available today is usable and expendable on several fronts, and lends itself to expanding its fields of application thanks to new technologies that will allow us to interface more and more, even at a distance, allowing all the “insiders” involved to act by updating and changing the model, for easier coordination of work.

SOLUTIONS AND RECOMMENDATIONS

New communication languages concerning the environment and cities have led and continue to lead the field of Urban Survey to rethink its methodological approaches and, in particular, the relationship between what can be measured, what is observed and perceived, and representation (De Carlo, 2016). The application of new technologies has, in fact, triggered a cultural transformation also in the field of urban survey research, opening it up to new interconnections with other sectors and fields of application, which require new methods of investigation and communication.

The potential offered by new computer systems and programmes and by means of communication allow the involvement of an ever-growing number of people through the web, with the need to use a language that everyone, even non “insiders”, can easily understand. Urban Survey studies must therefore be proposed through new ways of expression, subverting the tried and tested specialist languages towards a more popular and less sectorial representation.

In this increasingly evolved and fascinating scenario, however, there are some controversies. In this large-scale evolutionary process, which involves many sectors, interactive digital modelling is essential in order to support complex processes of knowledge and communication, because it facilitates them by working and expressing itself through forms, images and movements, capable of simulating reality and its possible transformations, but it is important to remember that urban reality consists not only of these elements. A city, a part of it or even just a building, or its environment, are also made up of intangible elements, linked to people and their way of living and relating to one another, which can be perceived only first-hand. What and where is the boundary between reality and the model of such a complex reality?

In other words: this link between the representation of reality and future scenarios is an added value in the field of design, but how much can one “control” a communication that can convey information? How can we control use that is always adequate when the possibility to act is extended across the web? The possibility to create scenarios between the real and the imaginary highlights a fragility which we have to be careful about: representation, design (to put it simply), have always had the same potential, to create images of what exists as well as those of pure fantasy. Representation, which has always been able to create from nothing configurations that neither necessarily exist nor are true, being able to skillfully influence the “modification” of reality to convey its perception, now takes on an even more delicate role, because of the difficulty in controlling information amplified by the web, which is not always used by the right people.

FUTURE RESEARCH DIRECTIONS

The contemporary trends of the research are increasingly oriented towards the ability to automate the processes of acquisition, recognition and classification of images, as well as those of modelling territories and cities.

The acquisition systems described above, which combine satellite shots with close-up aerial shots, contribute to the automation of urban system modelling processes. Also the consolidated tools of procedural modelling and shape grammar (Parish & Müller, 2001, Müller et al., 2006) and the more recent of inverse procedural modelling, devoted to the construction of models of existing cities (Weissenberg, 2014; Cura, Perret & Paparoditis, 2018) go in the same direction.

CONCLUSION

Given the reduction in times of acquisition and modelling and an ever increasing photorealistic and detailed rendering of the reality that goes hand in hand with the multiplication of visible data, the problem of the selection and interpretation of the data that have not been established, chosen and classified a priori arises, depending on the purpose of the survey.

Moreover, as we have seen, in most cases, the representation puts together tangible and intangible elements: the latter must be visualized using a homogeneous and recognizable language. From this point of view digital tools can offer layers' overlapping, information's interweaving, multi-scalar contents.

Therefore, the problem of data selection is shifting from the moment of analysis to that of synthesis and this is one of the problematic issues that will have to engage scholars who deal with Urban Survey in the coming years.

ACKNOWLEDGMENT

Although the chapter is the result of a shared research among the three authors, it must refer to the specialist work of: Cristina Boido: the Main focus of the article: International case studies and the Solutions and recommendations; Pia Davico: the Background and the Main focus of the article: Overview; Roberta Spallone: the Introduction, the Main focus of the article: An experimental research, and the Future research directions and conclusion.

KEY TERMS AND DEFINITIONS

3D Geometric Modelling: It is a modelling method based on points, lines, surfaces and volumes.

3D Modelling: 3D modelling is the process of developing a mathematical representation of any three-dimensional surface of object via specialized software.

3D Parametric Modelling: It is a modelling method that allows to maintain consistent relationships between elements as the model is manipulated.

BIM Modelling: Building information modelling (BIM) is a digital representation of physical and functional characteristics of a facility. A BIM is a shared knowledge resource for information about a facility forming a reliable basis for decisions during its lifecycle; defined as existing from earliest conception to demolition. BIM involves representing a design as combinations of objects that carry their geometry, relations, and attributes.

Database: A complex combination of structured data in tables that relate to one another, allowing the interactive management of information with automatic implementations, quick updates and specific interrogations.

GIS: Geo-referenced information system which allows the relation and organisation of geo-referenced data, favouring the update, enhancement, analysis, manipulation, and re-elaboration in map form.

Open Source: The term indicates software that is not protected by copyright, the source code of which (this being the part of the software that computer programmers can manipulate to alter the operation of a program or an app) is issued with a licence which makes it open to alteration or improvement by users.

Shape Grammar: Invented by Stiny and Gips (1972), it is an algorithmic system for creating and understanding designs directly through computations with shapes.

Addressing the New Pragmatic Methods in Urban Design Discipline

INTRODUCTION

Almost three decades before the beginning of the third millennium, the impacts of the “digital age” appeared and dominated most areas such as theories of journalism, teaching, foreign language education, new epistemologies, digital media, and digital fluency. Consequently, before the beginning of the twenty-first century, there were impacts on things like the faces of buildings, the design of public urban spaces, urban industry, urban mobility, urban policy, and integrating telecommunications. These effects have been apparent in most studies in the areas of planning and urban design and have become influential in the accuracy or weakness of the results, mainly in developing the cyber-cities, smart cities, smart growth, and digital urbanism. These influences have reached the point where most of the scientific forums have begun insisting on the application of new, innovative methods that rely on digital technologies along with developed conventional methods.

The primary goal will be to understand the importance of using research methods appropriate to the subject matter of the research and the desired results. Also, it intends to drive the researchers to develop their vision by using the traditional methods and seeking to integrate them with advanced technology research methods in their related work. This goal includes two objectives. The first is to highlight the importance of using both new and conventional methods together. The second is to present these selected analytical methods in a way that allows the readers to search for the other purposes associated with their research.

This chapter addresses new methods that display research problems which are strongly linked with two issues: urban form (UF) and spatial analysis (SA). It focuses on how to use these methods in an urban design discipline (UD), based on the dominant science and new analytical approaches, such as “virtual world design,” “spatial planning,” “geoinformatics,” “urban sensing,” and “a three-dimensional model of the city.” It reveals the methods that help the designer to measure people’s sensation in cities. These methods try to balance between two fundamental issues. The first is collecting data about city places in each survey about people’s behavior. The second is exploring the reliability and validity of these methods and measures by pragmatically applying them to the analysis of real-world problems.

The research methodology focuses on a bibliographic study, including application examples, based on a considerable number of academic research papers and official reports, publications dealing with some conventional and new pragmatic methods in urban planning and design discipline, as well as in the area of environment design. This study will first display the background theoretical approaches related

DOI: 10.4018/978-1-7998-3479-3.ch083

to the areas of planning and design, as an introduction to clarify the research methods that underpin the central theme.

Notably, this study is a bibliographic review of some new pragmatically methods in urban planning and design discipline. The organization of this chapter starts with a background for the key issues, and one episode has a connected view that includes six methods in two stages. The first displays two methods for measuring the visual aesthetic dimension, and the second consists of four methods for measuring the affective response approach. The conclusion states the definitive view and includes a proposal for future research.

BACKGROUND AND SETTINGS OF URBAN FORM AND SPATIAL ANALYSIS

Urban form is one of the most critical concerns of urban design. It focuses on the relationship between people and place in the built environment, with particular attention to the relationship between built-up mass and urban spaces. For decades, the specialists have devised several dimensions which govern these bilateral relations people-place and built-up mass-spaces. They are functional, social, economic, environmental, behavioral, aesthetic-visual, cognitive-perceptual, and temporal dimensions. Spatial analysis of urban spaces is one of the conventional analytical methods that urban design has used for measuring and analyzing the urban form, which was extended, based on Kevin Lynch's (1960) famous theory "the Image of the City".

In 1960, Kevin Lynch focused on the concept of the 'cognitive map' and conducted his first real-life experiments in Boston and Los Angeles, when he asked the residents to sketch out and bring back their daily routes from their memories. He presented the "way-finding" strategy, legibility and imageability to be a theoretical base for various studies. Afterwards, this strategy is transformed to be a tool, an approach, a quantitative analytical method, and a methodology. In these, they examine the spatial system and the configuration of the layout of the city. Furthermore, it explores the effects of this configuration on the organization of the uses within the city and the relations with the entire system.

Jerry Weisman (1981) and GD Weisman (1987) used the term of legibility based on the wayfinding method, to identify the ability of users to find their ways in the layout of the student' building and in housing for elderly people. John Peponis, Craig Zimring, and Yoon Kyung Choi (1990) developed this method to achieve a *more rigorous analytic description of building layout and exploration paths that exhibit their own pattern* (Peponis, Zimring, & Kuang Choi, 1990, p. 550). The wayfinding method has been used to study the structural properties of the building layout depends on developed the techniques of syntactic analysis, at University College London. Distinctly, the most common studies starting from Kevin Lynch's (1960) *The Image of the City*, Jerry Weisman's (1981) *Evaluating Architectural Legibility Way-Finding in the Built Environment*, Romedi Passini's (1984) *Wayfinding in Architecture*, GD Weisman's (1987) *Improving Wayfinding and Architectural Legibility in Housing for the Elderly*, John Peponis, Craig Zimring, and Yoon Kuang Choi's (1990) *Finding the Building in Wayfinding*, Paul Arthur and Romedi Passini's (1992) *Wayfinding: People, Signs, and Architecture*, Susan Hunter's (2010) *Design Resources: Spatial Orientation, Environmental Perception, and Wayfinding*, Gesine Marquardt's (2011) *Wayfinding for People With Dementia: The Role of Architectural Design..*

In the vein, according to Michael Mehaffy (2008), Christopher Alexander is one of the pioneers of the design method movement that aims to move systematically through sequential steps in an organized design process. The movement's response to the complexity of technical problems in the post-World War II era is fuelled by the development of computer science and programs. Instead, the new method should

incorporate an “argumentative process” within a network of issues. In the vein, according to Michael Mehaffy (2008), Christopher Alexander is one of the pioneers of the design method movement that aims to move systematically through sequential steps in an organized design process. The movement’s response to the complexity of technical problems in the post-World War II era is fueled by the development of computer science and programs. Instead, the new method should incorporate an “argumentative process” within a network of issues. After the first generations of design methods (the problems) and the second generation (argumentative process), the third generation (refutable hypotheses) emerged in 1980 with respecting the “plurality of views”. The third generation leads to the Christopher Alexander’s theory of pattern languages (1977).

The methods of quantitative analysis of urban spaces were introduced using new theories, including Bill Heller’s theory of the space syntax (SS) (Hillier, 1996). It describes layouts regarding the pattern of connections between spaces based on the “kinetic perception.” It was based on the idea that gathering information about the city comes through the movement and mobility within its streets (Jabbari, Fonseca, & Ramos, 2017).

The SS has emerged as a theory for the social use of space and virtual world design from since the early 1970s. Its applications are in the field of urban design in the “social field of vision,” and the cultural aspects of human behavior and communication in social spaces. It focuses on the study of spatial interrelationships between people’s interactions to explore the “social distances”, and distinct levels of intimacy (Hillier, 1996; Hillier & Hanson, 1997; Morello & Ratti, 2009). The SS (Batty, 1991, 1997; Hillier & Hanson, 1984, 1996; Peponis & Wineman, 2010) started as a theory for studying the configurational properties of cities.

Since 2000s, the innovative approaches have emerged to address issues related to the human soul and their emotional responses, and the human sensory assessment using sensor technologies concerning humans’ perception of spaces and emotional reactions in real time. The information related to emotion was used in the urban planning of the concept of smart city (Choudhury, Pradhan, & Kar, 2016; Matei, Ball-Rokeach, & Qiu, 2001; Sagl, Resch, & Blaschke, 2015). Susan Hunter (2010) sees that “researchers studied how the layout of built structures influenced human emotions and movement” (p. 2).

In 2015, Peter Zeile, Bernd Resch, Linda Dörrzapf, Jan-Philipp Exner, Günter Sagl, Anja Summa, and Martin Sudmanns, in their research entitled *Urban Emotions—Tools of Integrating People’s Perception into Urban Planning* used conventional methods, such as “mental maps and psycho-geography” with “the field of digital emotion-based urban tagging” (Choudhury et al., 2016, p. 27). Moreover, Bernd Resch (2013) Choudhury et al. (2016) believe that the term urban motion used the concepts of “people as sensors” and “urban tagging.” Also, the specialists could understand the concept of smart city through new bio-statistical and sensor technology. Urban motion depends on the spatial planning, geographic information systems, concepts of computer linguistics, sensor technology methods, and real-world data. It uses:

1. the spatial monitoring approach based on sensor driven data gathering and human sensory assessment. Monitoring includes deductive monitoring by observation and inductive monitoring through crowd sourcing processes.
2. The Psycho-physiological monitoring approach for measuring the arousal of the citizens, based on the body reaction. It uses the gathering of bio-sensor, bio-statistical, and physiological data.

PRAGMATICAL METHODS: CONVENTIONAL ALONGSIDE TECHNICAL

This section discusses two sets which are related to the concept of spatial analysis. The first set focuses on the visual-aesthetic dimension which handles several terms and concepts, such as wayfinding, imageability, and walkability. It addresses two urban planning and design analytical methods, starting from the 1960s. The second set focuses on the fields of urban design based on earlier science and new analytical approaches, such as virtual world design, spatial planning, geoinformatics, urban sensing, and a three-dimensional model of the city. Modern technological innovations have helped to develop scientific research methods.

Some of these innovations are geographic information science, communication techniques, modern wireless telecommunications (i.e., general packet radio service), the third-generation mobile phone system, universal mobile telecommunications system, wireless local area network, actuators, radio-frequency identification tags, remote sensing, mobile phones, Internet technologies, developed mobile technologies, ubiquitous mobile computers, GPS trajectories (Resch, Summa, Sagl, & Zeile, 2015; Choudhury, Pradhan, & Kar, 2016). They discuss the affective dimensions. For instance, it stimulates human feelings when someone visits a place for the first time, which is known as the “urban affective atmosphere.” In this regard, the first investigation should be about the meaning of addressing or using “new methods” to display research problems which are strongly linked with the issue of “urban emotions” and affective atmosphere. Particularly, the issues of urban emotions have been discussed repeatedly in the fields of environmental psychology, urban sociology, and urban planning.

This section reviews six methods dealing with the emotional information in the context of urban planning and design starting from the year of 1960. These methods can be classified as follows 1) wayfinding (1960), 2) Space Syntax (1970), 3) Human Sensory Assessment (2000), 4) Urban Sensing: people as sensors (2008), 5) Crowdsourcing approach cognitive appraisal (2008), and 6) The Internet of Things (IoT) (2010).

Two Methods for Measuring the Visual-Aesthetic Dimension

Based on people’s intuitive ability, four components of controlling the aesthetic appreciation include:

1. **Sense of Rhythm and Pattern:** Large affinity, similarity, contributing to character, and identity.
2. **Appreciation of Rhythm:** Stricter repetition: contributing to visual pleasure.
3. **Recognition of Balance:** Visual scene, and order related to harmony.
4. **Sensitivity to Harmonic Relationships:** A coherent whole (Carmona, Heath, Oc, & Tiesdell, 2003, p. 131). It includes two methods: The wayfinding approach (Lynch, 1960) and the SS.

The Wayfinding Approach: The First Method

This method is followed by the real-world design through involving people in monitoring the city components. It depends on the concept of cognitive maps that Kevin Lynch devised in 1960 to perceive “the image of the city.” These maps include five key elements: Districts, landmarks, paths, edges, and nodes. Also, the maps include people’s feelings of the place, and this approach evolves to include three criteria: Legibility (clarity), imageability (visual image), and wayfinding (direction). Legibility is easy for anyone to recognize the parts of a city and can also organize them in “a coherent pattern” (Lynch, 1960, p. 2). This means that the city is organized in a way the person can easily read the cohesion of

the city parts. The legible elements make the city easier for the viewer to interact with the context and to establish a relationship that allows him/her to come to the place each time and reach his/her goals quickly. This helps him/her not to lose the direction, track, or destination to reach. Each time, through this reading, the viewer has a visual experience that makes him/her remember the place through an event or situation, or even through the building itself. For any viewer, the imageability explains the degree of clarity of the mental image of the city, it is a physical object, reflected from its character and quality. Whenever the quality and character of the city is reliable, then the opportunity to evoke a strong image in the observer has high probability. The shape, colour, and arrangement are involved in the creation of clear and robust mental images of the environment. Also, it helps “*the making of vividly identified, powerfully structured, and highly useful mental images*” (Lynch, 1960, p. 9). Kevin Lynch presented wayfinding as a tool to create the image of the city. Through reshaping cities, Lynch’s goal is to give a form that organizes the context (Lynch, 1960, p. 90) that depends on “*how well people are able to find their way to their particular destination without delay or undue anxiety*” (Peponis, Zimring, & Kuang Choi, 1990, p. 561).

Several empirical ways allow to analyse the wayfinding performance: a) Self-report, b) the ability to locate places on a plan of the premises, c) the proportion of subjects which are able to be reached of a particular destination (quantify), and d) direct observation, but it is relatively rare (Peponis et al., 1990, p. 560). Constantly, people tend to orient themselves towards urban spaces that are easily accessible. These urban spaces should be legible by the following three elements. The first is the “structural properties of buildings layout. The second is the configurational properties, rather than the merely rely on the landmarks, signs, or other cues. The last is the data that should reflect the distinction between the general understanding of layouts and the search for specific destinations (Peponis et al., 1990, p. 556). The configuration properties refer to several aspects which are:

- The way in which spaces are related to one another.
- The overall pattern that constitute of these spaces.
- The overall pattern that emerges from pairwise connections, rather than elements or single connections taken by themselves (Peponis et al., 1990, p. 558).

In 1992, at the University of Montreal, Paul Arthur, as an architect, and Romedi Passini, as an environmental psychologist, developed the term “wayfinding” to be used in a framework of collaboration of cognitive architecture (Arthur & Passini, 1992). The wayfinding is the environmental stimuli (i.e., intersection, stairs, and billboard) that orients people’s choices and behaviours (e.g., turn right, go up, and look for information) (Arthur & Passini, 1992, p. 31). The wayfinding becomes a tool to the information-gathering and decision-making processes. It used to orient and let people move easily through a space as Susan Hunter (2010) describes by “how people get from one place to another” (p. 1). Moreover, in this method, the cognitive space is classified as a topological space; people identify the relative locations, rather than the direction or distance (Hunter, 2010, p. 3). The result is that people’s cognitive maps about the surroundings are articulated based on the information which comes from their knowledge (Hunter, 2010, p. 3).

Space Syntax: The Second Method

This theory deals with the city as a living being. Also, it is a spatial analysis of many urban spaces that provide reliable information in the observers’ perception, whether they are residents or visitors. The

idea of this method is based on the “kinetic perception,” or what we can call the “sequential movement-cognitive.” People’s sense of the city is done by perceiving each segment as a prelude for realizing the whole, and this realization is carried out through multiple space trips within the city. The viewers move through the spaces and are aware of the place, then they move to another space. Each movement has different information and different awareness; this flow continues until people have a full understanding of one trip, and then of a series of tours. This method was based on the idea of gathering information about the city comes through the movement and mobility within its streets (abbari, Fonseca, & Ramos, 2017, p. 23). The observations that the movement arises create the mental image of the city. Therefore, this theory develops the method of axial maps, which rely on the analysis of roads network, the relations with each other, and land use overlooking them. In this theory, the focus of the urban analysis is the “city spaces and their organization” to give approximately 60–80% of the pedestrian and vehicular movement pattern (Saif Haq & Girmay Berhie, 2017, pp. 5-6). The SS method is used to analyse the spatial configuration of the city based on “how the urban system functions” (Kayvan Karimi, 2017, p. 1). These methods are used in many fields (Jabbari et al., 2017, p. 23; Kayvan Karimi, 2017, p. 1), as shown in (Figure 1).

Figure 1. Space syntax timeline of methods and field of research. Source: the authors

In the early 1970s, the University College London presented the SS theory to discuss the social use of space, followed by the fields of virtual world design. In architectural and urban design, the SS presents the applications to study spatial interrelationships between people’ interactions, particularly in the “so-

cial field of vision,” and the cultural aspects of human behaviour and communication in social spaces. Mainly, the SS allows to explore the “social distances” that enable diverse types of human activity and distinct levels of intimacy in the interrelationship between human beings (Hillier, 1996, p. 64; Hillier & Hanson, 1997; Morello & Ratti, 2009, p. 838). For Hillier and Hanson (1997), this concept becomes an approach to examine the reasons of why buildings and the built environment acquire this spatial form. This approach searches about why buildings and built environments were as they were and occupied only a small corner of the theoretically vast field of architectural and urban possibility. Notably, the initial studies of this approach dealt with “the organic settlements” and “vernacular buildings”; it tried to show the formal, spatial, and functional forces that generate their characteristics of the spatial forms. The SS as an approach focuses on the “perceptual dimension” of urban spaces, through a continuous observation journey in the place for a specific period of time and has to do with the nature of the structural structure of the target location. It is based on providing “a digital image of the city” and its area is “remote sensing” and “spatial information science.”

In 2008, the SS defined as “a methodology,” studied two aspects of the spatial system of the city: a) The connective relationships for the entire system, and b) the global connective properties of each element. Also, it was used as “a tool” to examine the nature and function of the activity that should be found in a specific place through its degree of relevance to the local context, as well as its relevance to the public context (Mehaffy, 2008, p. 61; Wineman & Peponis, 2010, p. 90). This process includes two phases: Phase I-Indicators of structural characteristics analysis and Phase II-Axial maps and lines analysis.

Phase I-Indicators of Structural Characteristics Analysis. This method reviews the characteristics of the structure to the case study starting the city levels, through a combination of indicators. It focuses on the following six indicators:

1. **Intelligibility:** It is an indicator that shows the degree at which people can see some places directly and create a subjective experience without any effort. It implies that places cannot be seen and tested for the same place in the same way.” Any system that can be extrapolated” means that its spaces are well connected and integrated. Conversely, the area that cannot be read is connected, but not integrated. Thus, the area does not drive the visitor well (Hillier, 1996, pp. 129, 171; Morello & Ratti, 2009, p. 845; Wineman & Peponis, 2010, p. 90).
2. **Connectivity Index:** It is concerned with the extent of communication between the components of the project. It is the study of the patterns of connections through the relationship of each spatial unit or line to its immediate adjacent. Also, it measures the flexibility of movement that a specific space should provide through the number of axes of movement linked to each other.
3. **Synergy Index:** It is the interaction and cooperation of two or more elements to create a joint effect, greater than the sum of their separate effects. This indicator measures the flow of traffic, based on the correlation coefficient, which shows the relationship between local and global integration. This indicator is concerned with measuring the residents’ privacy and isolating them from visitors through the urban structure.
4. **Integration Index:** It is the relationship of each spatial unit or line to the entire set of other units or lines that constitute the spatial system that is studied and measured. It measures “the relative position of space or axial line vis-a-vis the general pattern of the building configuration” (Peponis et al., 1990, p. 567). This indicator measures the extent to which the components of the study area are compatible with each other and for their inhabitants or visitors, according to changes in transitions and change over time. Technically, “integration” and “choice” indicate the complex values for

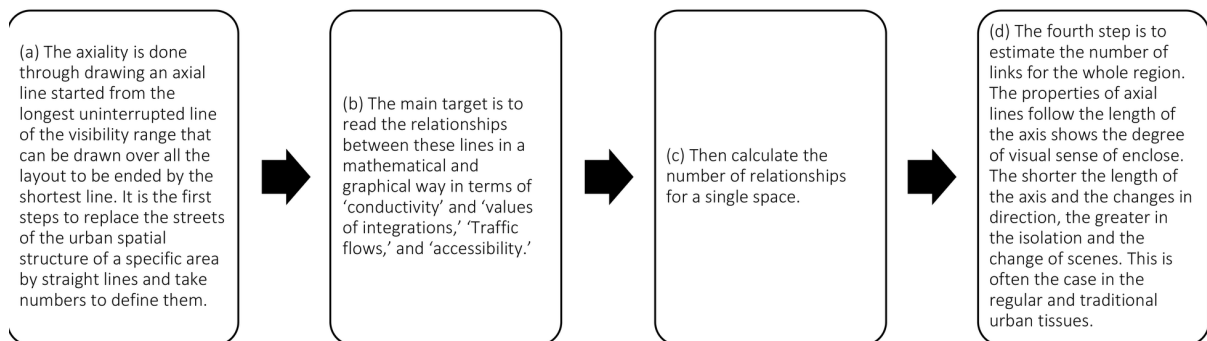

each “unit area or space.” It means a measure of “closeness” and “how close space is, on average, from all other spaces in that network” (Saif Haq & Girmay Berhie, 2017, p. 6).

5. **Spatial Openness Index:** It is used to reinterpret the two-dimensional city image through a three-dimensional analysis; it depends on the relation between social dimension and the built environment (Dalton & Bafna, 2003; Morello & Ratti, 2009). The index is defined as (a) the volume of the part of a surrounding sphere which is visible from a given point of view, and (b) the net volume of open space. It is determined by the quality of perception and comfort based on the perceived density (Morello & Ratti, 2009, p. 842) to consider the notion of “intelligibility” that explains the quality of an environment (Dalton & Bafna, 2003, pp. 1-59).
6. **Intensity Index:** It measures the intensity of the use of the axes by the resident population and visitors, and, in theory, the more axes of movement associated with each other, the less density on each axis.

Phase II-Axial and Convex Maps and Lines Analysis by Using Iso-Visi-Matrix. For the SS, based on the concept of the convex space partitioning (the simply axial mapping), the “continuous space” is converted into “a connected set of discrete units.” Hillier (1984, pp. 97-98) generated the convex map of the spatial structure that is partitioned into a set of “fewest and fattest” convex spaces. The convex map is the most elementary unit of analysis that comprises the fewest and fattest convex spaces. It has two-dimensional extensions directly visible from each segmental point. Convex spaces are the largest units that can be fully perceived at one time within a building and can be taken to represent the “local constituents” of a layout (Peponis, Zimring, & Kuang Choi, 1990, p. 566).

This method discusses the implications of two issues. The first is the prediction of pedestrian traffic in residential areas and their relation to the motorised traffic through accessibility, traffic flows, and wayfinding. The second is the patterns of residents’ and visitors’ collective behaviour to estimate how much crime can occur in the area. The steps of drawing an axial and convex map are listed in Figure 2. The significant consequence of this map is showing how vital each “vacuum” is to the structure that gives the affinity or isolation to the population’. This way may be useful when comparing two or more streets through reading the clarity, regular communication, and integration in deciding the feelings of belonging to the place, familiarity, fear, and safety.

Figure 2. Steps of space syntax. Source: the authors

Tandy (1967) presented the notion of “isovist” in the field of landscape geography. An isovist is the set of all points visible from a given vantage point in space and concerning the environment (Benedikt,

1979, p. 47). The shape and size of an isovist are subject to change with position. Numerical measures that quantify some salient size and shape features are proposed. It is known as (a) “the field of view, available from a specific point of view,” and (b) the area not in the shadow cast from a point light source (Morello & Ratti, 2009, p. 839). Also, “an isovist is the sum of the infinite number of lines of sight (or axial lines) that pass through a single point in space (usually at eye level) and found in the same plane (usually parallel to the ground level)” (Morello & Ratti, 2009, p. 839). Isovist is the volume of visible space from a given point in the area, together with a specification of the location of that point. Sets of isovists and isovist fields form an alternative description of the environments. This method is related to the behavioural and perceptual studies in the field of architecture. Furthermore, it focuses on several issues, which are the areas of view control, privacy, defensibility, dynamic complexity, and spaciousness (Benedikt, 1979, p. 47).

The spatial units for syntactic analysis are based on the visibility polygons or isovists, which is “the field of view” available from a specific vantage point; a horizontal slice through this field of view is then calculated, usually taken at eye height and parallel to the ground plane (Benedikt, 1979). The two characteristics describe each polygon as, on the one hand, a visibility polygon covers all points that can be linked to a given root point by a visibility line. This line is not interrupted by any boundary. On the other hand, the vision thresholds that share the polygon of vision about all other locations is in the same pattern (Wineman & Peponis, 2010, p. 89).

The software is used to fill all navigable spaces within the area of study with a grid of vantage points and to generate visibility (eye-level isovists) or accessibility (floor-level isovists) polygons from each of these locations. Each of these polygons that are created from the grid of vantage points can be characterised by a series of properties that include area, perimeter, minimum, mean, and maximum radial length. Once the grid polygons have been calculated, the researcher can examine the relationship between each polygon generating point and every other generating point to develop a set of “syntactic” measures (Wineman & Peponis, 2010, p. 89). When visibility polygons, or isovists, are drawn at eye level, they capture the objective properties of the visual field as structured by the affordances of the environment (Wineman & Peponis, 2010, p. 89). A three-dimensional matrix of urban visibility (i.e. a “3-D isovist”) “defines the 3-D field of view, which can be seen from a vantage point with a circular rotation of 360 degrees and from the ground to the sky” (Morello & Ratti, 2009, p. 842).

Four Methods for Measuring the Affective Response

Similar to James Russell (2003, 145–149), the current work discusses concepts of the primary emotional impact such as the core affect, perception of affective quality, and attributes. It describes many of the everyday feelings. The effect is the simplest raw (non-reflective) reaction to the feelings and mood, which is described as a neurophysiological state. In this, the affective quality is a property of the stimulus. The attributed effect covers the reactions, liking, displeasure, motives, and empathy. Affective response is presented by a person, either perceived as neutral, moderate, or extreme. When a person is responding to a particular situation, the response is twofold as emotional and conscious experience. The first is the emotional experience when it is affected by the moderate or extreme; it can be consciously experienced as pleasant or unpleasant and form the basis of an emotional experience. The second is the conscious experience. When the effect is milder, it influences the conscious experience and the behaviour in a less direct way. In this case, the effect is experienced in the background—as the property of the environment. Both types of experience can diagnose the environment, but the first is complex and difficult to measure

and is linked to mood and feelings (Klettner, Huang, Schmidt, & Gartner, 2013, p. 66), (Resch, Summa, Sagl, & Zeile, 2015, p. 202).

This approach is diagnostic of the affective responses to space and examines the emotional qualities of environments (i.e., hectic, exciting, or beautiful). It includes an innovative approach to collecting the affective responses towards space (Klettner, Huang, Schmidt, & Gartner, 2013, p. 67), (Figure 3). In this approach, the process includes two methods: a) deductive—the observation of phenomena over a time span, and b) inductive—an expression of crowdsourcing processes in the bottom-up planning mode (Zeile, et al., 2015, p. 907). ARA includes four methods: human sensory assessment (HSA), urban sensing (US), Crowdsourcing, and The Internet of Things (IoT) (Abusaada & Elshater, 2019a).

Figure 3. The affective responses to space that examines the emotional qualities of environments. Source: the authors

Human Sensory Assessment: The Third Method

The human sensory assessment has appeared at the beginning of 2000 as a subjective method of the data collection concerning humans' perception of spaces and emotional reactions in real-time through using sensor technologies. This approach follows the field research of mass communication, media, sociologists, and criminologists regarding ethnically diverse residential communities. Based on the modelling of the Geographic Information System (GIS), mental maps, and spatial-statistical, Sorin Matei et al, (2001, p. 431) presents an approach for mapping the feelings of fear in the city of Los Angeles. They also produced the "emotional maps" based on the model of "*a dimensional Virtual Reality Modelling Language*." It strives at granting a better understanding of the environment.

Urban Sensing (People as Sensors): The Fourth Method:

This method focuses on the emotional cartography & bio-mapping. By using the internet (e.g. Wikimedia, OpenStreetMap, and Google Earth) and by using the developed mobile technologies or communication techniques. Urban Emotions is a trans-disciplinary, an interdisciplinary, human-centred approach that treats "people as sensors" to involve them in planning processes (Choudhury, Pradhan, & Kar, 2016, p. 27). It is the psycho-physiological approach to measure the arousal of people, depends on the data about the change in the body reactions (physiology) of people. It refers to gathering of the bio-sensor, biostatistical and physiological data (the startle reflex of the body, reflex of the neck or the eye) (Zeile, et al., 2015, p. 907). It is used to extract contextual emotion information from the data of technical sensor

and human sensor. The results can be used in urban planning for decision support and the evaluation of ongoing planning processes. It depends on the ground-truthing emotion measurements through people as sensors, the type of emotion, and the cause why an emotion occurred, the context of the emotion (Resch, Summa, Sagl, & Zeile, 2015, pp. 204-205). Most current sensors see a person's "additional heart rate", skin conductance, body temperature—the latter two variables are counter rotating, i.e., in case an emotional spike occurs, skin conductance rises, and body temperature drops because the person emits cold sweat (Resch, Summa, Sagl, & Zeile, 2015, p. 204). This method provides feedback to real-world processes in urban management and planning that will help to detect previously unseen urban patterns (Resch, Summa, Sagl, & Zeile, 2015, p. 210). In 2008, Christian Nold was the first one who combined emotional data with the help of physiological parameters (skin resistance level) and GPS in his project Bio mapping/emotion mapping. He used the wearer's Galvanic Skin Response (GSR) records, which is an indicator of emotional arousal in conjunction with their geographical location. It explores the implications of visualising intimate biometric data and emotional experiences using technology. Notably, the "use of the internet in combination with georeferenced data and ubiquitous mobile computers can be described as the next evolutionary step of the Internet, the 'Geoweb' or 'Web 3.0'" (Bergner, Exner, Memmel, Raslan, Talal, Taha, & Zeile, 2013, p. 409). This method uses some psychological studies that discuss the causes of changing the inner feelings of people. The documenting the feeling comes from the influence of the body (emotion or conscience). Scholars were able to measure these effects using some modern techniques that combining methods of "the spatial planning," "geo-informatics/ GIScience/ geographical information systems (GIS)," "computer linguistics," "sensor technology methods," and "an emotion-tracking technique." (Li, Hijazi, Reinhard Koenig, Zhong, & Schmitt, 2016). The process merges the concepts of semantic, geographic, temporal distance, semantic, geographic, and temporal clusters (Resch, Summa, Sagl, & Zeile, 2015, p. 210). The tool of this approach is as follow: measurements from calibrated bio-sensors, subjective observations. The general Urban Emotions concept includes four steps in two groups (Figure 4) (Resch, Summa, Sagl, & Zeile, 2015, p. 201).

Figure 4. The two groups and the four steps in each concept of urban emotion. Source: the authors

Crowdsourcing Approach Cognitive Appraisal: The Fifth Method:

This approach uses the cognitive assessment of the internet technologies and GIS. Alexey Tarasov et al. (2010) describe the crowdsourcing approach has tasks outsourced to a large group of non-expert individuals. This approach focuses on the context of labelling corpora, which is used in a field of machine translation, computer vision, and sentiment analysis. It is used to collect people's affective responses towards space. This approach depends on the investigation and collection of information by individuals who are not connected to each other, through the use of virtual reality sites on the Internet and reality. Assessing essential qualities of urban space with emotional and visual data based on the model '...for measuring emotions is based on the concept of cognitive appraisal, which categorises a relatively complex set of secondary emotions' (Li, Hijazi, Reinhard Koenig, Zhong, & Schmitt, 2016, p. 3).

The Internet of Things (IoT): The Sixth Method

This method is a novel paradigm that is rapidly gaining ground in the scenario of the modern wireless telecommunications. The basic idea of this concept is the pervasive presence around us of a variety of things or objects (e.g. Radio-Frequency Identification (RFID) tags, sensors, actuators, mobile phones, etc.). Through a unique addressing scheme, the method can interact with each other and cooperate with their neighbours to reach common goals (Atzori, Iera, & Morabito, 2010, p. 2787) (Giusto, Iera, Morabito, & Atzori, 2010). Besides, the method is considered an ecosystem powered by sensors and microchips, which enables connection and communication among real-world objects, environments, software, and people. This network of things, sensors and devices are capturing and exchanging enormous amounts of data and fueling the Big Data movement. And, "[t]he functionality of the IoT depends upon four fundamental steps: data acquisition, information extraction, knowledge extraction, and action-taking (L'Heureux, Grolinger, Higashino, & Capretz, 2017, p. 74). A smart environment is one of the relevance of this approach; it is "that making its employment" easy and comfortable things to the intelligence of "contained objects to be an office, a home, an industrial plant, or a leisure environment." It creates a) comfortable homes and offices. Furthermore, this method is used in the industrial plants, a smart museum and gym (Atzori, Iera, & Morabito, 2010, pp. 2795-2796).

CONCLUSION

This chapter referred to one of the most scientific aspects of the progress that may be the specialists in the fields of urban planning and design made in last few decades. This progress has been very clear on the track of developmental planning and design methods from the beginning of the sixties until now. Nowadays, it is reflected in the methods of testing in urban studies and research regarding its suitability, while also considering the circumstances of this technological age. Thus, various advanced ways emerged over the last three decades in the field of urban planning and design, as it has aimed to achieve accurate findings more than before. As a result, many modern trends in planning and design turned towards building the future cities based on the concepts of smart growth, the smart city, and the eco-city. All of them have been characterized as "intelligent" by the use of digital-based technology; they depend on intelligent buildings, smart urban citizens, smart environments, smart lifestyles, smart economies, and smart governance, as well as a smart integrated supply system for infrastructure. With the building of

these types of cities, digital-based technology has also emerged in smart energy, smart utilities, smart and integrated transportation, mobility system, and smart parking.

Two directions were considered in an example of the conventional and advanced research methods in this work. The first focused on how the urban planners and designers employ visual aesthetics and perceptual dimensions. The second direction deals with the new methods which employ the affective/emotional dimension by using digital tools. The review gave the following results:

- Two methods are included in the first set. The first is the contribution of Kevin Lynch (1960). He used the wayfinding as a method which revolves around how to guide people within the built environment, depending on the visuospatial representations of the city. Afterwards, specialists used the term of legibility based on the wayfinding method, such as: Jerry Weisman (1981); GD Weisman (1987); John Peponis, Craig Zimring, and Yoon Kyung Choi (1990); Paul Arthur and Romedi Passin (1992); Susan Hunter (2010). The second method presents a theory to study spatial interrelationships between people's interactions, called space syntax, by Bill Hillier and Julienne Hanson. It started as a concept in the early 1970s and became an approach in 1967, when it focused on the perceptual dimension of urban spaces. In 2008, it became a methodology and a tool. These methods are still developing to date.
- The second set of research focuses on the affective response approach, particularly humans' perception of spaces and emotional reactions. It started in the 2000s and includes human sensory assessment urban sensing, crowdsourcing, and the Internet of Things. These methods focus on emotional cartography and bio-mapping, the data of technical sensor and human sensor, semantic, geographic, and temporal distance, semantic, geographic, and temporal clusters, sentiment analysis, the concept of cognitive appraisal, and modern wireless telecommunications.

Nowadays, various tools depend on several digital technology and visualization methods and techniques:

- Integrating dynamic urban development simulation models and 3D visual urban simulation in visual impact analysis includes scale models, photo simulation, computer-aided design graphics, and video simulation. For instance, it has been used in urban planning and design disciplines to follow the public participation of historic preservation including visual impact analysis.
- Spatial planning, geoinformatics, geographical information systems, computer linguistics, sensor technology methods, and an emotion-tracking technique.
- The Internet web: Wikimedia, OpenStreetMap, Google Earth, and Web-based visualization technologies.
- Developed mobile technologies or communication techniques.
- Radio-frequency identification tags, sensors, actuators, and mobile phones.

These innovative methods and more should be considered in future research concerning the outgrowths of digital technology in the field of architecture in rehabilitation of traditional and historic cities, as well as in the process of design thinking and the planning of new cities. Prominently, it should consider not only physical dimensions but also non-physical aspects to establish future cities and sustainable and smart cities.

FUTURE RESEARCH DIRECTIONS

The current study confirmed that each research problem requires a specific method to extract the results. Nowadays, various new methods and techniques can be used in the field of urban planning and design such as (1) Isovist analysis 1979, (2) Visual Graph Analysis, or VGA 2001, (3) Vision-guided Agent-Based Modelling 2002, (4) Body Mass Index (BMI) 2002, (5) Segment-angular spatial network analysis 2005, (6) Place Syntax, a combined accessibility and the urban environment elements analysis tool 2008, (7) Origin-destination weighted network analysis to advance the methods of spatial accessibility analysis 2012, (8) Topological, angular, and metric radii of space syntax analysis (DepthmapX) 2011-2015, (9) GIS-linked tools and software to generate and use the space syntax analysis within a GIS environment 2015, (10) Axial integration map, (11) The multi-criteria analysis (MCA) 2016, (12) Wearable Technologies: concepts, methodologies, tools, and applications (2018).

These innovative methods and more should be considered in future research concerning the outgrowths of digital technology in the field of architecture in the area of rehabilitation of traditional and historic cities, as well as in the process of design thinking and the planning of new cities. Prominently, it should consider not only physical dimensions but also non-physical aspects to establish future cities and sustainable and smart cities.

KEY TERMS AND DEFINITIONS

Pragmatic Method: Depends on the philosophy that inspires people to attend for a way and do the things by the best to achieve their aspired intentions and ends.

Research Method: A discipline deals with the principles and techniques of scientific interrogation, includes three approaches: quantitative, qualitative, and mixed methods.

Spatial Analysis: A research paradigm to explain the patterns of human behavior and their spatial expression through analyzing the events of a location or place, by focuses on two ways: buffering and overlaying.

Urban Emotion: An interdisciplinary and trans-disciplinary psycho-physiological approach and method; it provides feedback to real-world. People are the sensors focusing on the data about the change in body reactions. UE is to extract contextual emotion information from the data of “technical and human sensor” for decisions support and the evaluation of ongoing planning and design processes.

Urban Form: Consequences of two parts of the built environment (masses and spaces), which emerges in three-dimensional configuration of the physical characteristics related different scales. It responds to

the total societal impacts of the built environment: functional, socio-cultural, economic, behavioural, temporal, political, environmental, and technological dimensions.

Urban Sensing: Investigate the dynamics of the city considering people as sensors related the social networks in the community. It focuses on urban computing to handle the data through ubiquitous computing techniques.

Wayfinding: A strategy, approach, quantitative analytical method, and methodology to explore the spatial system and the configuration of the layout of the built environment, as well as it examines the effects of this configuration on the organization of the functions of the situation and the relations with the entire system.

Reengineering Legacy Systems Towards New Technologies

Djelloul Bouchiha

Center University of Naama, Algeria & EEDIS Lab. UDL-SBA, Algeria

INTRODUCTION

Software reengineering is an important area of the software engineering. The quest to maintain and understand operational legacy systems has always been a challenge for software practitioners. This chapter presents a compilation of notions and techniques covering major areas namely, reverse engineering, program understanding, software maintenance, migration and evolving. Our objective is not to create new terms, but to introduce the terms already in use with different perspectives.

Before starting with the reengineering of legacy systems towards new technologies, we must know: in which research field are we working? Which research community do we belong to? What research issue are we dealing with?

To answer all these questions, we use the ACM Computing Classification System (CCS). It has been built as a hierarchical ontology that can be used in semantic Web applications. It relies on a semantic terminology as the main source of concepts and categories that present the state of the art of the computing discipline. The 2012 ACM CCS (ACM-CCS, 2012) starts with thirteen computing fields. Browsing this hierarchy to attempt our goal gives us the following tree.

Figure 1. Reengineering issues in the ACM CSS classification

DOI: 10.4018/978-1-7998-3479-3.ch084

Leaves of the presented tree in Figure 1 are the sub-issues in relation to the reengineering problem, according to the ACM CSS classification.

The following sections give more details about the reengineering process, notably prerequisites, model, problem statement, taxonomy, techniques and future trends. We also list some specialized conferences and journals. Finally, we give conclusion and advices to the researchers belonging to the software engineering community.

BACKGROUND

This chapter is titled “Reengineering Legacy Systems towards new Technologies”. Here, the term “System” is used to say “software system” not the hardware one. “Legacy systems” are systems currently in use, and have been often left to run for a long time without too many significant changes. “New technologies” are the latest (current) technologies.

Reengineering is discussed in this chapter as sub-issue of Software Engineering which is described as the application of engineering techniques to produce software that runs properly and is constructed in an efficient manner. The produced software should be efficient, reliable, modifiable, testable, reusable, maintainable, portable, interoperable and correct. Software engineering process consists of a set of activities, known as the software lifecycle. Principal activities are: requirements analysis, design, implementing and testing the software. Requirements analysis phase consists in determining precisely what the functionality of the system will be. The design phase consists in taking the requirements and devising a representation to allow the requirements to be translated into source code. The implementing activity is the most familiar to students that consists in writing the program source code. Software testing consists in checking the software before it is judged ready to be released to its customer.

Reengineering is the study and analysis of an existing system for purposes of understanding, maintenance, or migration towards new technologies (Chikofsky & Cross, 1990). Based on the software lifecycle described above, the next section presents a general model for the software reengineering process.

REENGINEERING MODEL

We propose, in Figure 2, a general model for software reengineering that depicts the sub-processes for all levels of the reengineering process.

Figure 2. General model for software reengineering

Reengineering starts with the source code of an existing software (legacy system), and finishes with the source code of a target system. This is done through three sub-processes: **(1) Abstraction** is a gradual increase in the abstract level of system. This upward movement is called Reverse engineering. **(2) Alteration** is changing the system representation at the same level of abstraction. According to the abstraction level, it can be *recoding* (at the implementation level, to translate the existing code to a target language), *redesigning* (at the design level) or *respecifying* (at the requirement level). **(3) Refinement** is a gradual decrease in the abstract level of system. This is termed forward engineering.

In fact, the reengineering process involves maintenance or migration, according to the used activities:

Example 1: going from the legacy system (*implementation*) to the *design* abstraction level where we correct some errors (*repairing*), and then we return to the implementation with the same language: this is maintenance process.

Example 2: going from the legacy system (*implementation*) to the *design* abstraction level, then we alter the design representation (*redesign*), and finally we generate a new code with a new language: this is a migration process.

PROBLEM STATEMENT AND PROPOSED SOLUTION

In this section, we answer the question: Why do we need software reengineering?

So the reengineering process aims at migrating, maintaining or understanding legacy systems (Alam & Padenga, 2010):

1. *Migration issue:* the number of legacy systems currently in use is very high. These systems cannot be abandoned because they are applications in which companies have already invested considerable time and money.

Existing software may be based on hardware platforms, operating systems, or languages that might have become obsolete. On the other hand, the computer industry is growing at a fast rate; new hardware and software systems with new features, quickly outdating legacy systems and thus replacing them with new systems built from scratch can be disruptive. Therefore, it will be more rational and economic to reuse and adapt legacy systems to these new technologies.

2. *Maintenance issue:* over time and with multiple changes in the existing software system, it will be of low quality. As maintenance and changes of the software continue, its reliability steadily decreases to the point of being unacceptable.

Legacy systems lack a good design structure and code organization, making changes to the software difficult and costly. Enhancements of the functionality of the existing systems may also be needed.

3. *Understanding issue:* the difficult part lies in understanding of the existing system. In most cases the requirements, design and code documentation will be no longer available, or will be out of date, so it is really not clear what functions are to be moved. In most cases the original developers of the legacy systems are not available to verify or explain the system; the only available source is the current software source code.

For these reasons, companies with working software that meets their needs might need to migrate to new hardware platform, operating system or language. So, a reengineering process is required to migrate our existing systems into more advanced platforms that are easier to maintain.

Reengineering process consists in taking existing software that have become expensive to maintain or whose system architecture or implementation are now obsolete, and redoing it with up to date technology. It allows taking legacy systems, and generating a new target system that preserves the required functionality, while applying new technologies. It allows also increasing reliability, improving maintainability, reducing the cost of maintenance, and preparing for functional enhancement.

The reengineering process is mainly characterized by its inputs. This is why we propose in the next section the inputs taxonomy.

REENGINEERING INPUTS TAXONOMY

The procedure for classifying reengineering approaches of the legacy systems is generally based on their inputs. Inputs are resources that can be used to generate data and control models, which in turn can be used in the subsequent steps of the reengineering process. This process starts from the implementation level where there exists often data and program code.

After going through various literatures in the reengineering field, we were able to propose reengineering inputs taxonomy as depicted in Figure 3.

Figure 3. Reengineering taxonomy according to the system Inputs

At the first level, the reengineering process can be classified into two categories, according to the system input:

1. *Data-driven Reengineering process*: relational, XML... data can be analyzed using Application Interfaces (API), in order to recover data models (class diagram, entity-relationship model ...) at the reverse engineering stage. In the literature, recovering data models is often called “database reverse engineering”.

For XML files, the DTD (Document Type Definition) and XML schema play a very important role in the reverse engineering process, as they provide a very important resource from which a data model

can be constructed. For a relational DB, it is the relations (tables) and integrity constraints (Domain constraint, primary keys, foreign keys ...) that play this primordial role.

Mapping rules from entity-relationship to relational model (Bouchrika, 2014), or from class diagram to relational model (Ambler, 2000), can be used inversely to recover data models.

2. *Program-driven Reengineering process*: according to their objective, code fragments can be classified into two sub-categories:
 - a) Control code: program understanding techniques are used to analyze
 - Data scripts (SQL Queries): allow recovering data models from SQL queries (Select, Insert...) imbedded in the source code.
 - Control scripts (Control structures): allow recovering control models (activity diagram, system architecture, workflow models...) from iterative control (loops), conditional control (if-then-else, case)...
 - b) Presentation code: HTML tables, lists and forms, can be analyzed with API, in order to recover data models (class diagram, entity-relationship model, schema, DOM...).

We can't leave this section without providing descriptions of the terms used above:

Application Interface (API): an applicative layer used as intermediate between the application and resources. So, it aims at exploring data. For example JDOM Java API is used to explore HTML and XML files.

Model, Diagram & Schema: in literature there is ambiguity between these three terms.

- Model: is the result of an abstraction of a part of the real world; modeling is the abstraction process.
- Diagram: is a graphical representation of the model, for example class diagram in UML.
- Schema: the term schema is often related to another term. For example: XML schema, Database schema, electrical schematic, etc. In databases, the term "schema" refers to the organization of the database. So the schema describes the structure of the database. It indicates which tables (relations) constitute the database, as well as the attributes included in each table.

Why HTML tables, lists and forms are used as reengineering Inputs? because they are the most used elements to represent structured data on the Web. Tables and lists are used as data output, and Forms as data input.

PROGRAM UNDERSTANDING TECHNIQUES

Program-driven reengineering process, described in the previous section, needs program understanding techniques. Müller (1996) defines *program understanding* (PU) or **program comprehension** as "the task of building mental models of the underlying software at various abstraction levels, ranging from models of the source code itself to ones of the underlying application domain for maintenance, evolution and reengineering purposes".

Many techniques have been developed to help the analyst to understand existing programs:

1. Pattern matching: allows looking for patterns in the program source code.
2. Variable dependency graph: is a graph that represents relations between the variables.
3. System dependency graph analysis: is a program representation used by program slicing.
4. Program slicing: is a decomposition technique that extracts from a program, statements that come into play in a particular computation.
5. Graphical visualization of program: some aspects of the program architecture can be represented as graphs.

Pattern matching:

Patterns are known as plans, cliches, motifs, molds, templates, string... Whatever the name, pattern aims to identify predefined structure in the program source code.

A Pattern Definition Language can be used to describe the patterns. For example, pattern of the Select SQL query can be defined as follows:

```
Select <attribute>*
from <table>*
where (<column> = <value>)*;
```

Tilley et al. distinguish between structural and behavioral patterns, depending on whether one is looking for code that has a specified syntactic structure, or searching for code components that share specific data-flow, control-flow or dynamic relationships (Tilley, Paul, and Smith, 1996).

The remaining program understanding techniques use, all of them, directly or indirectly, pattern matching to achieve their objectives.

Variable dependency graph:

In the variable dependency graph (VDG), each variable of the program is represented as a vertex, while an arc (directed or not) represents a direct relation (assignment, comparison, etc.) between two variables.

To construct this graph, it is only needed to look for definite statement patterns in the program.

Figure 4 shows the analyzed fragment of the program in (I), the used patterns to recognize relations between variables in (II), and the resulting VDG in (III).

Figure 4. Example of variable dependency graph (VDG)

A path, between variable A and variable D in the graph, reflects the existence of a sequence of statements in the program such that the value of A is in relation with the value of D.

The interpretation of “the variable A being in relation with the variable D” can be one of the following: the two variables belong to the same domain or share the same values, the two variables denote the same real world object, there is a dependency between the two variables, etc.

System dependency graph:

The system dependency graph (SDG) is an extension of the program dependency graph (PDG).

A- Program dependency graph

While VDG represents dataflow, PDG represents the control flow.

A PDG is a directed graph, where vertices correspond to statements and control predicates, and edges correspond to data and control dependencies.

A control dependence edge from vertex X1 to vertex X2 means that the execution of the statement X2 depends on the evaluation result of the predicate X1.

A data dependence edge from vertex X1 to vertex X2 means that the program’s computation might be changed if the relative order of the components represented by X1 and X2 were reversed.

Figure 5 shows a program fragment (I) and its corresponding program dependency graph (II). The solid arrows represent control dependence edges, and the dashed arrows represent data dependence edges.

Figure 5. Example of program dependency graph (PDG)

Note that control dependences connect always the entry vertex (BEGIN) with the procedure’s statements and predicates.

B- System dependency graph

Horwitz et al. introduced the term system dependency graph (SDG) for the dependency graphs that represent multi-procedure graphs (Horwitz et al., 1990).

A system dependency graph (SDG) includes a program dependency graph (PDG), which represents the system's main program, and procedure dependency graphs, which represent the system's auxiliary procedures, and some supplementary edges. These supplementary edges are of two sorts: (1) edges that represent direct dependencies between a procedure call site and the called procedure, and (2) edges that represent transitive dependencies due to procedure calls.

Figure 6. Example of system dependency graph (SDG)

Figure 6 shows a program fragment (I) and its corresponding system dependency graph (II). Red arrows represent the supplementary edges. A solid red arrow is between the call site and the called procedure, and dashed arrows represent data dependence edges between program statements and procedure statements.

Program slicing:

Program slicing is a decomposition technique that extracts statements from a program (source code) that are relevant to a particular computation.

Informally, a slice answers the question “Which are the program statements that potentially affect the computation of variable X at the point A?”; so a slice of a program consists of all statements and predicates that might affect the value of X at the point A.

The task of computing program slices is called program slicing.

Program slicing uses the system dependency graph (SDG) to represent the program, and an algorithm (Horwitz, Reps and Binkley, 1990) to compute the slice.

Number of methods to compute slices have been proposed. A distinction is defined between static and dynamic slicing methods. The difference between static and dynamic slicing is that dynamic slicing admits a fixed input for a program, whereas static slicing does not make any assumption regarding the input.

Graphical visualization of the program:

Among graphs that can help understanding programs, Henrard in (Henrard, 2003) cites:

- Inter-program call graph: the vertices represent programs and the edges represent the call between programs.
- Intra-program call graph: represents the call relations between procedures in the program.
- Database usage graph: vertices are of two types (programs and the collections of entity-type), and edges link programs with the collections entity-type they use.
- JCL graph: represents the sequence of execution of the different programs with the files they use. Vertices are programs or files, and edges represent program sequences and file usage.
- Hyperlink graph: vertices represent documents, and edges represent the hyperlinks between these documents. This kind of graph can be used for the Web documents.

In the next section, we present a reengineering process based on models.

MODEL DRIVEN ENGINEERING (MDE)

One of the most important conceptual tools to implement a reengineering process is MDE. The model-driven engineering (MDE) is a generative process enabling to get, treat and produce information from other data derived from structured entities called models. MDE settings are mainly based on modeling, meta-modeling and transformation aspects. Another important MDE aspect is the conformity relationship. A model conforms to the meta-model as a program conforms to the programming language's grammar in which it is written. This means that a meta-model describes the different types of model elements and how they are arranged.

Therefore, the MDE is considering models and software as first class entities. The model represents any aspect of software, and it consists of a set of model elements.

Figure 7. A model-based transformation process according to MDE

Figure 7 shows a model-based transformation process. It allows transforming any source model Ma that conforms to MMa (source meta-model), into a target model Mb that conforms to MMb (target meta-model). The transformation is driven by a set of rules expressed as transformation model, which itself conforms to a transformation meta-model (Bezivin, 2006).

In the next section, we cite some specialized conferences and journals in the software engineering field.

SPECIALIZED CONFERENCES AND JOURNALS

In literature, there are many peer-reviewed journals and international conferences, where articles are published in the software engineering field. In peer-reviewed (refereed) journals or conferences, articles are reviewed by several experts in the field before they are published, in order to ensure their quality.

The following graph presents ranking information about some important Software Engineering conferences. This information has been summarized with help of SJR (Scimago Journal & Country Rank) (SJR, 2018).

Figure 8. Histograms of Software Engineering conferences ranking

“H Index” means that H papers have been published. Each one has been cited in other papers at least H times. “SJR” (SCImago Journal Rank) indicator indicates the average number of weighted citations of the conference proceedings. “Cites per Document” column indicates the average citations per document. “Total Cites” column corresponds to the number of citations in the selected year.

Figure 8 shows that **ICSE (International Conference on Software Engineering)** is the most important one. Since 1975, ICSE is a software engineering conference that provides a forum for researchers to propose and discuss recent innovations, trends, experiences and concerns in the field of software (re) engineering.

On its Web site (<http://www.icse-conferences.org/>) you can find all information about the ICSE conference series. You find also useful information for organizing the future ICSE conferences.

Table 1 explains more about the scope of the conferences presented in Figure 8.

Table 1. Conferences' scope

Conference	Aims and Scope
International Conference on Software Engineering (ICSE)	ICSE presents and discusses the most recent innovations, experiences, trends and concerns in the field of software engineering.
the ACM SIGSOFT Symposium on the Foundations of Software Engineering (FSE)	FSE presents and discusses the most recent innovations, trends, experiences, and challenges in the field of software engineering.
International Symposium on Software Reliability Engineering (ISSRE)	ISSRE covers reliability engineering for software. Reliability engineering is a sub-discipline of software engineering that emphasizes dependability in the lifecycle of a product.
Euromicro Conference on Software Maintenance and Reengineering (CSMR)	CSMR aims at uniting divergent groups of software maintenance professionals and academic software engineers via the addition of commercial suppliers.
Asia-Pacific Software Engineering Conference (APSEC)	APSEC aims to bring together researchers and practitioners from industry, academia, and government to encourage wider collaboration between academics and industries and to advance the state of the art in Software Engineering field.
the Australian Software Engineering Conference (ASWEC)	ASWEC attracts contributions that cover the whole spectrum of software engineering research and practice. It provides an opportunity for interaction between industry practitioners and software engineering researchers.
Software Engineering Education Conference (SEEC)	SEEC is looking for contributions that address challenges, innovations, and best practices in software engineering education.
International Symposium on Empirical Software Engineering and Measurement (ISESEM)	The objective of ISESEM is to provide a forum where researchers, practitioners, and educators can report and discuss the most recent research results, innovations, trends, experiences, and concerns in the field of empirical software engineering and metrics.

With the same principle, Figure 9 presents ranking information about the some specialized journals in the software engineering field, also with help of SJR (Scimago Journal & Country Rank) (SJR, 2018).

It is clear that the **IEEE Transactions on Software Engineering (TSE) journal** has the best ranking in terms of H index and cites per document. However, **Advances in Engineering Software (AES) journal** is a powerful competitor, when we conceder SJR and Total cites factors.

IEEE Transactions on Software Engineering journal focuses on well-defined theoretical results and experimental studies that have potential impact on the development, analysis and management of software. Its scope ranges from developing principles to applying those principles to specific environments.

The **Advances in Engineering Software journal** is interested in recent and projected advances in computer-based engineering techniques. It covers several fields, such as mechanical, aerospace, civil and environmental engineering, while concentrating on research and development leading to practical problem-solving.

Table 2 explains more about the scope of the journals presented in Figure 9.

Figure 9. Histograms of Software Engineering journals ranking

FUTURE RESEARCH DIRECTIONS

In the last ten years, some works focus on Web reverse engineering (Bouchiha, Malki & Mostefai, 2009a; Benslimane, Malki & Bouchiha, 2009). Web application is a software system that provides its functionality through the Web (Conallen, 1999). For their goal, most of these Web application reverse engineering approaches adapted techniques of database reverse engineering to generate conceptual schema.

In (Perez-Castillo, Garcia-Rodriguez, Caballero, Polo & Piattini, 2009; Bouchiha, Malki & Mostefai, 2009b; Niiyama, Chung, Chinn & Davolos, 2008; Bouchiha, Malki & Mostefai, 2008; Takonewa, Mamello & Paul, 2010), researchers aim at constructing Web Services from existing Web applications. Web Services are software components that provide services via a standardized interface. As a consequence, Web applications can be easily integrated to each other in a business-to-business schema to provide a more valuable service to users.

Actually, the trend is to build a technology stack to support a “Web of data”, which is the sort of data found in databases, instead of the “Web of documents”. The ultimate goal of the Web of data is to enable machines to do more useful works, and to develop systems that can support trusted interactions over the Web. The term “Semantic Web” refers to W3C’s vision of the Web of linked data (W3C, 2018a). Semantic Web technologies enable users to create data stores on the Web, build vocabularies, and write rules for handling data. Linked data (Berners-Lee, 2006) are empowered by technologies such as RDF (Resource Description Framework) (W3C, 2018b). Several attempts have addressed the issue of reengineering legacy systems, notably Web applications, into Semantic Web (Lehmann et al. 2014;

Table 2. Journals' scope

Journal	Aims & Scope
IEEE Transactions on Software Engineering (TSE) (https://www.computer.org/web/tse)	TSE is interested in well-defined empirical studies and theoretical results that have potential impact on the analysis, construction, or management of software.
ACM Transactions on Software Engineering and Methodology (TOSEM) (https://tosem.acm.org/)	The scope of TOSEM includes models, methods, mechanisms, languages, and tools for the evaluation, elaboration, and evolution of products and processes all along the software lifecycle, from requirements specification to software maintenance.
Advances in Engineering Software (AES) (https://www.journals.elsevier.com/advances-in-engineering-software)	The scope of AES includes innovative computational strategies for large-scale engineering issues, analysis and simulation methods and systems, etc.
Empirical Software Engineering (ESE) (https://www.springer.com/computer/swe/journal/10664)	ESE aims at promoting the publication of industry-relevant research, since one of its aims is to address the significant gap between research and practice.
Automated Software Engineering (ASE) (https://link.springer.com/journal/10515)	ASE details research papers, tutorials, surveys and accounts of significant industrial experience in the foundations, techniques and tools of the software engineering technology.
IET Software (IETS) (https://digital-library.theiet.org/content/journals/iet-sen)	IETS publishes papers on all aspects of the software lifecycle, including design, development, implementation and maintenance. The focus of the journal is on the methods used to develop and maintain software, and their practical application.
International Journal of Software Engineering and Knowledge Engineering (IJSEKE) (https://www.worldscientific.com/worldscinet/ijseke)	IJSEKE covers areas relating to software engineering and knowledge engineering. The scope of the journal includes object-oriented systems, logic programming, rapid prototyping, and software and knowledge-ware maintenance.
Annals of Software Engineering (AOSE) (https://www.springer.com/computer/swe/journal/10480)	AOSE covers all aspects of software engineering. This includes Computer-Aided Software Engineering, Human Factors in Software Engineering, etc.
Innovations in Systems and Software Engineering (ISSE) (https://link.springer.com/journal/11334)	ISSE addresses problems and innovations in Software Engineering, Systems Integration, Software Development and other related fields.
International Journal of Agent-Oriented Software Engineering (IAOSE) (http://www.inderscience.com/jhome.php?jcode=IAOSE)	IAOSE fosters discussion on all software engineering aspects of the use of agent technology for the development of IT systems. This includes Software engineering methodologies for agents, MAS and agreement technologies, etc.
International Journal of Software Engineering and its Applications (IJSEIA) (http://www.sersc.org/journals/IJSEIA/)	IJSEIA aims at facilitating and supporting research related to software engineering and its applications. The scope of the journal includes Agent Technology, Aspect-Oriented and Feature Interaction, etc.
Journal of Software Engineering (JSE) (https://scialert.net/jhome.php?issn=1819-4311)	JSE is dedicated to publish original and significant results in all areas of software engineering. The scope of the journal includes methods and practices, object-oriented systems, rapid prototyping, etc.

Nagy et al. 2011; Mulwad, Finin & Joshi, 2013; Scharffe et al. 2012; Munoz, Hogan & Mileo, 2014; Cresci et al., 2014; Bouchiha, Malki, Alghamdi & Alnafjan, 2017).

The recent technological overhangs have focused on the miniaturization of communication devices, like Smartphone, in wireless networks. In this new hardware context, Ubiquitous Computing is a paradigm whose goal is to allow users to access data, and make them available anywhere and at any time. Pervasive Information Systems (PIS) constitute a category of Software Systems working in the Ubiquitous Computing environment. PIS cover a dynamic and complex environment instead of personal

computers only, perceive contextual information instead of simple user input, and support mobility instead of stationary services. Authors of (Hauser, Günther, Flath & Thiesse, 2017) pointed out the need to convert legacy systems to PIS. Our chapter suggests a set of reengineering techniques that can be used to address this issue.

CONCLUSION

Reengineering is the study and analysis of legacy system in order to understand, maintain or migrate it towards new technologies. In this chapter, definitions, techniques and even a list of specialized conferences and journals have been introduced; all of them concern the software reengineering research field. Illustrative models have been proposed and relevant questions have been answered to highlight the ways to authors who are interested in writing research papers or surveys about software reengineering.

We note that it is very difficult to write surveys about software engineering fields. So we advice authors of research papers to cite only works in relation with their ultimate goal (maintenance, migration, understanding...), and with the input and output of their proposed process (models, source code...). Evaluation, and specially comparison, is also difficult because of lack of common corpus, on which experiments can be done. Researchers have to choose their own corpus, which should be open access, and they can use some metrics, like those used in information retrieval (RI), notably Recall, Precision and F-measure. In the Evaluation step of a software engineering process, the expert intervention is always needed.

Finally, we hope that the readers, especially those belonging to the software engineering community, find this chapter useful as it provides an indicative overview of the concepts and tools in the area of software reengineering. The mastery of all these tools will provide significant incremental enhancement to software productivity.

KEY TERMS AND DEFINITIONS

Design Recovery: Creating design abstractions from a combination of source code, existing design documentation (if available), etc.

Forward Engineering: Moving from the high-level abstractions and logical implementation-independent designs to the low-level physical implementation of a system.

Migration: Transporting legacy systems to a newer platform (hardware or operating system) or language. For example move from a mainframe to a network-based computing environment. Migration focuses on conserving legacy systems functionalities in new environments. This needs eventually *restructuring* or *refactoring*.

Redocumentation: Creation or amendment of a semantically equivalent representation in the same relative abstraction level. It aims at recovering documentation about the subject system. It may give more explanation with alternate views such as dataflow, data structure and control flow.

Reengineering: The examination and alteration of a subject system in order to reconstitute it in a new form, and the subsequent implementation of this new form (Chikofsky¹ & Cross, *IEEE Software*, January 1990). Reengineering involves both reverse engineering and forward engineering, and it has two main objectives: (1) Software maintenance that involves *repairing* (corrective) errors or *improving* (perfective) with new required functionalities. (2) Software migration that aims at *evolving* (adaptive) systems to new environment. In particular, the reverse engineering phase may aim at *understanding* (predictive) the system.

Refactoring: Changing the source code and preserving the behavior (in the object-oriented programming).

Restructuring: The transformation from one structure to another at the same relative level of abstraction: while preserving the external behavior (functionality and semantics) of the subject system. Restructuring allows changing structure without changing functionality. It can be performed based on the knowledge of structural form; however, it does not require understanding its meaning. For example, converting a set of If statements into a Case structure, or converting *While* loop to *For* loop.

Reverse Engineering: The analysis of a subject system to identify its components and their inter-relationships, and to create its representations in another form, or at higher level of abstraction. Two subareas of reverse engineering are widely referred: *redocumentation* and *design recovery*.

Software Maintenance: Modifying a software system after delivery to correct its faults to improve its performance or other attributes, or to adapt the system to a changed environment.

ENDNOTE

¹ Elliot J. Chikofsky is described in the literature as the developer, organizer, and evangelist of software engineering automation. He is most known for his advocacy of reverse engineering and CASE technologies. He is also a consultant on management issues and information systems development methods, tools, and design techniques.

A Comprehensive Update and Performance Evaluation of Friction Factor Formulae

INTRODUCTION

Water and solutions are used in many technological and engineering processes (chemical, mechanical, water treatment and distribution, biomedical and pharmaceutical processes). Movement of these essential materials in the reservoir is channeled by the conservation of mass, momentum, and energy. Applications of these movements range from the low-temperature condition in gas liquefaction to high temperatures and pressures in rocket momentum systems. Actual design of all these processes requires an accurate knowledge and values of the fluid transport parameters in the pipeline and channel systems. In a specific situation, viscosity of the liquid, diameter of the pipes and tubes coupled with the friction factor are needed to calculate headloss and energy requirement in the channel and pipeline systems. A precise value of friction factor is necessary in the computation of headloss and the energy. In mechanical, chemical, water supply and biomedical processes, numerous factors are involved in the pipe network and liquefied transport systems. In medical sciences and biomedical engineering, conveyance of a physiological liquid takes place through the catheter tube into the body of a human being, which indicates that accurate computation of F_f in the catheter is a significant factor to discharge adequate liquid. Some of these significant design factors in the pipeline systems are the lengths, diameters and F_f of the pipes, water level in the reservoirs, head-discharge characteristics of the pump, water demands at different nodes and performance characteristics of different valves and minor elements in the pipe systems (Gupta and Bhawe, 2007; Özger and Yıldırım, 2009a; 2009b).

Parts of these parameters in pipe network systems remain fixed at different periods of the pipe, while some parameters would fluctuate during the life span of the pipe systems. The fluctuating parameters can be considered to be imprecise parameters. Basic equation for computing the head loss in the pipe network and pipeline system is either Hazen-Williams or Darcy-Weisbach equation that requires calculation of F_f . Darcy – Weisbach equation is expressed as follows:

$$h_L = \frac{\lambda L V^2}{2gD} \quad (1a)$$

DOI: 10.4018/978-1-7998-3479-3.ch085

$$h_L = \frac{8\lambda L Q^2}{g\pi^2 D^5} \quad (1b)$$

where; h_L is the head loss; λ is the F_f ; L is the length of the pipeline or pipe system; D is the diameter of the pipe; V is the mean velocity in the pipeline or pipe system; g is the acceleration due to gravity and Q is the flow (discharge) in the pipeline or pipe system.

Colebrook – White's formula presented an implicit expression for calculating F_f . The expressions are (Colebrook and White 1937; Colebrook, 1939; Mahendra, 2008; Mehran and Ayub, 2011; Oke *et al.*, 2015a):

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{2.51}{R_e \sqrt{\lambda}} \right) \quad (2a)$$

$$\frac{1}{\sqrt{\lambda}} = 1.74 - 2 \log_{10} \left(2 \frac{k}{D} + \frac{18.7}{R_e \sqrt{\lambda}} \right) \quad (2b)$$

$$\frac{1}{\sqrt{\lambda}} = 1.14 - 2 \log_{10} \left(1 + \frac{9.3}{R_e \frac{k}{D} \sqrt{\lambda}} \right) + 2 \log \left(\frac{D}{k} \right) \quad (2c)$$

where; λ is the friction factor; k is effective roughness size of the pipe wall and R_e is the Reynolds number.

Estimations and computations of exact values of F_f in the pipe networks are bedrock in many engineering applications (transfer of liquid and solutions through chemical reactors as well as in industrial processes which involve single-phase, double-phase). In health and medical sciences, and biomedical engineering processes, solutions flow are attained at high flow rate in blood vessels. These solutions are transported through catheter tube into the body of patients, which requires accurate value of F_f (Shaikh *et al.*, 2015). It has been shown that computation of accurate value of F_f requires an implicit equation known as Colebrook – White's formula. This implicit equation needs the use of numerical algorithms that are complex and not as fast as the explicit equations. In hydraulics of complex and supercritical pipe-flow systems it is difficult to use Colebrook – White's formula, which indicates that reliable F_{ff} are preferred. The needs for more robust and accurate F_{ff} have led researchers to propose and develop new F_{ff} . Today in mechanical, hydraulics, fluid and other engineering, there are various explicit formulae, which present a varying degree of accuracies depending on the complexity of their functional forms. It has been stated that the most complex F_{ff} usually provide higher efficiency and there is the need to establish accuracy of these F_{ff} (Özger and Yıldırım, 2009a; Shaikh *et al.*, 2015). These are F_{ff} found in literature. Moody (1944; 1947):

$$\lambda = 0.0055 \left(1 + \left[20000 \frac{k}{D} + \frac{10^6}{R_e} \right]^{\frac{1}{3}} \right). \quad (3)$$

Altshul (1952):

$$\lambda = 0.11 \left(\frac{k}{D} + \frac{68}{R_e} \right)^{0.25}. \quad (4)$$

Wood (1966):

$$\lambda = a + b R_e^{-c}, \quad (5)$$

Where; a,b and c are Wood constants as follows:

$$a = 0.094 \left(\frac{k}{D} \right)^{0.225} + 0.53 \left(\frac{k}{D} \right), \quad (6a)$$

$$b = 88.0 \left(\frac{k}{D} \right)^{0.44}, \quad (6b)$$

and

$$c = 1.62 \left(\frac{k}{D} \right)^{0.134}. \quad (6c)$$

Barr (1972) suggested an expression of the form:

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{5.1286}{(R_e)^{0.89}} \right). \quad (7)$$

Eck (1973):

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\left(\frac{k}{3.715D} \right) + \left(\frac{15}{R_e} \right) \right). \quad (8)$$

Churchill (1973):

$$\frac{1}{\sqrt{\lambda}} = -2 \left(\log_{10} \left(\left(\frac{k}{3.71D} \right) + \left(\frac{7}{(R_e)} \right)^{0.9} \right) \right) \quad (9)$$

Jain (1976):

$$\frac{1}{\sqrt{\lambda}} = -2 \left(\log_{10} \left(\left(\frac{k}{3.715D} \right) + \left(\frac{6.943}{R_e} \right)^{0.9} \right) \right) \quad (10)$$

Swamee and Jain (1976);

$$\lambda = \left[\frac{0.25}{\left(\log_{10} \left(\frac{k}{3.7D} + \frac{5.74}{(R_e)^{0.9}} \right) \right)^2} \right] \quad (11a)$$

$$\sqrt{\lambda} = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{5.74}{(R_e)^{0.9}} \right) \quad (11b)$$

Churchill (1977):

$$\lambda = 8 \left[\left(\frac{8}{R_e} \right)^{12} + \frac{1}{(B_i + A_i)^{\frac{3}{2}}} \right]^{\frac{1}{12}}, \quad (12)$$

$$A_i = \left(-2.457 \log_e \left(\left(\frac{k}{3.7D} \right) + \left(\frac{7}{R_e} \right)^{0.9} \right) \right)^{16}, \quad (12a)$$

$$B_i = \left(\frac{37530}{R_e} \right)^{16}. \quad (12b)$$

Chen (1979):

$$\frac{1}{\sqrt{\lambda}} = -2 \left(\log_{10} \left(\left(\frac{k}{3.7065D} \right) - \left(\frac{5.0452}{R_e} \right) \log_{10} \left(\left(\frac{1}{2.8257} \right) \left(\frac{k}{D} \right)^{1.1098} + \left(\frac{5.8506}{(R_e)^{0.8981}} \right) \right) \right) \right). \quad (13)$$

Round (1980):

$$\frac{1}{\sqrt{\lambda}} = 1.8 \log_{10} \left(\frac{R_e}{0.135 R_e \left(\frac{k}{D} \right) + 6.5} \right). \quad (14)$$

Barr (1981) suggested an expression of the form:

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{5.158 \log \left(\frac{R_e}{7} \right)}{R_e \left(1 + \frac{R_e^{0.52}}{29} \left(\frac{k}{D} \right) \right)^{0.70}} \right). \quad (15)$$

Zigrang and Sytsester(1982):

$$\lambda = \left[-2 \log_{10} \left(\frac{k}{3.77D} - \frac{5.02}{R_e} \left(\log_{10} \left[\frac{k}{3.77D} - \frac{5.02}{R_e} \left\{ \log_{10} \left(\frac{k}{3.77D} + \frac{13}{R_e} \right) \right\} \right] \right) \right) \right]^{-2} \quad (16)$$

Haaland (1983);

$$\frac{1}{\sqrt{\lambda}} = -1.8 \log_{10} \left(\frac{6.9}{R_e} + \left(\frac{k}{3.7D} \right)^{1.11} \right). \quad (17)$$

Serghides (1984),

$$\lambda = \left[A - \frac{(B_s - A_s)^2}{(C_s - 2B_s + A_s)} \right]^{-2}, \quad (18)$$

$$A_s = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{12}{R_e} \right), \quad (18a)$$

$$B_s = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{2.51A}{R_e} \right), \quad (18b)$$

$$C_s = -2 \log_{10} \left(\frac{k}{3.7D} + \frac{2.51B}{R_e} \right). \quad (18c)$$

Tsal (1989),

$$\lambda = 0.11 \left(\left(\frac{k}{D} \right) + \frac{68}{R_e} \right)^{0.25}. \quad (19)$$

If $\lambda < 0.018$ then $\lambda = 0.85\lambda + 0.0028$

Manadilli (1997):

$$\frac{1}{\sqrt{\lambda}} = -2 \left(\log_{10} \left(\left(\frac{k}{3.7D} \right) + \left(\frac{95}{(R_e)^{0.983}} \right) - \left(\frac{96.82}{R_e} \right) \right) \right). \quad (20)$$

Romeo *et al.* (2002):

$$\frac{1}{\sqrt{\lambda}} = -2 \left(\frac{\log_{10} \left(\left(\frac{k}{3.7065D} \right) - \left(\frac{5.0272}{(R_e)} \right) \right) \log_{10} \left(\frac{k}{3.827D} \right) - \left(\frac{4.567}{(R_e)} \right) \times}{\log_{10} \left(\left(\frac{k}{7.7918D} \right)^{0.9924} - \left(\left(\frac{5.3326}{(208.815 + R_e)} \right)^{0.9345} \right) \right)} \right). \quad (21)$$

$$\frac{1}{\sqrt{\lambda}} = \left(-1.8166 \log_{10} \left(\left(\frac{k}{4.1165D} \right)^{1.0593} + \left(\frac{7.0367}{(527.620 + R_e)} \right)^{0.9619} \right) \right)^{1.0131} \quad (22)$$

$$\frac{1}{\sqrt{\lambda}} = \left(-2.0064 \log_{10} \left(\left(\frac{k}{3.6795D} \right) - \left(\frac{4.8738}{R_e} \right) \log_{10} \left(\left(\frac{k}{4.2678D} \right)^{1.0287} + \left(\frac{7.4964}{(420.15 + R_e)} \right)^{0.9426} \right) \right) \right)^{0.9989} \quad (23)$$

Sonnad and Goudar (2004):

$$\frac{1}{\sqrt{\lambda}} = 0.8686 \log_e \left(\frac{0.4587 R_e}{s \left(\frac{s}{s+1} \right)} \right) \quad (24a)$$

$$s = 0.1240 R_e \left(\frac{k}{D} \right) + \log_e (0.4587 R_e). \quad (24b)$$

Sonnad and Goudar (2006):

$$\frac{1}{\sqrt{\lambda}} = 0.8686 \log_e \left(\frac{0.4587 R_e}{\left(s - 0.31 \right) \left(\frac{s}{s+1} \right)} \right). \quad (25a)$$

$$s = 0.1240 R_e \left(\frac{k}{D} \right) + \log_e (0.4587 R_e). \quad (25b)$$

Vatankhah and Kouchakzadeh (2008):

$$\frac{1}{\sqrt{\lambda}} = 0.8686 \log_e \left(\frac{0.4587 R_e}{\left(s - 0.31 \right) \left(\frac{s}{s+0.9633} \right)} \right), \quad (26a)$$

$$s = 0.1240 R_e \left(\frac{k}{D} \right) + \log_e (0.4587 R_e). \quad (26b)$$

Buzzelli (2008):

$$\frac{1}{\sqrt{\lambda}} = A_b - \frac{\left(A_b + 2 \log_{10} \left(\frac{B_b}{R_e} \right) \right)}{1 + \frac{2.18}{B_b}}, \quad (27a)$$

$$A_b = \frac{\left(\frac{0.744 \log_e (R_e) - 1.41}{\left(1 + 1.32 \sqrt{\frac{k}{D}} \right)} \right)}{\left(1 + 1.32 \sqrt{\frac{k}{D}} \right)}, \quad (27b)$$

$$B_b = \left(\frac{k}{3.7D} \right) R_e + 2.51 A_b. \quad (27c)$$

Avci and Kargoz (2009):

$$\lambda = \left(\frac{6.4}{\left(\log_e (R_e) - \log_e \left(1 + 0.001 R_e \frac{k}{D} \left(1 + 10 \sqrt{\frac{k}{D}} \right) \right) \right)^{2.4}} \right), \quad (28)$$

Evangelides *et al.* (2010):

$$\lambda = \frac{\left(\frac{0.2479 - 0.0000947 (7 - \log_{10} R_e)^4}{\left(\log_{10} \left(\frac{k}{3.615D} + \frac{7.366}{R_e^{0.9142}} \right) \right)^2} \right)}{\left(\log_{10} \left(\frac{k}{3.615D} + \frac{7.366}{R_e^{0.9142}} \right) \right)^2}. \quad (28)$$

Brkic (2011)

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\left(\frac{k}{3.71D} \right) + \left(\frac{2.18 S_b}{R_e} \right) \right); \quad (29a)$$

$$S_b = \log_e \left(\left(\frac{R_e}{1.816 \log_e \left(\frac{1.1 R_e}{\log_e (1 + 1.1 R_e)} \right)} \right) \right). \quad (29b)$$

Brkic (2012)

$$\frac{1}{\sqrt{\lambda}} = -2 \log_{10} \left(\left(\frac{k}{3.71 D} \right) + \left(10^{-0.4343 S_b} \right) \right); \quad (30a)$$

$$S_b = \log_e \left(\left(\frac{R_e}{1.816 \log_e \left(\frac{1.1 R_e}{\log_e (1 + 1.1 R_e)} \right)} \right) \right). \quad (30b)$$

Danish *et al.* (2011)

$$\frac{1}{2\sqrt{\lambda}} = A_d - \left(\frac{1.73718 A_d \log_e A_d}{1.73718 + A_d} \right) + \left(\frac{2.62122 A_d (\log_e A_d)^2}{(1.73718 + A_d)^3} \right) + \left(\frac{3.03568 A_d (\log_e A_d)^3}{(1.73718 + A_d)^4} \right) \quad (31a)$$

$$A_d = 4 \log_{10} (R_e) - 0.4, \quad (31b)$$

Fang *et al.* (2011) for smooth pipes:

$$\lambda = 0.25 \left[\log_{10} \left(\frac{150.39}{R_e^{0.98865}} - \frac{152.66}{R_e} \right) \right]^{-2}. \quad (32a)$$

Fang *et al.* (2011) for smooth and rough pipes:

$$\lambda = 1.613 \left[\log_e \left(0.234 \left(\frac{k}{D} \right)^{1.1007} - \frac{60.525}{R_e^{1.1105}} + \frac{56.291}{R_e^{1.0712}} \right) \right]^{-2}. \quad (32b)$$

Ghanbari *et al.* (2011) known as Ghanbari-Farshad-Rieke

$$\lambda = \left(-1.52 \log_{10} \left(\left(\frac{k}{7.21D} \right)^{1.042} + \left(\frac{2.731}{R_e} \right)^{0.9152} \right) \right)^{-2.169}. \quad (33a)$$

Shaikh *et al.* (2015)

$$\lambda = 0.25 \left[\log_{10} \left(\frac{2.51}{\alpha R_e} + \frac{k}{3.7D} \right) \right]^{-2}. \quad (34a)$$

$$\alpha = 1.14 - 2 \log_{10} \left(\frac{k}{D} \right), \quad (34b)$$

Offor and Alabi (2016a and b)

$$\lambda = \left(-2 \log_{10} \left(\left(\frac{k}{3.71D} - \frac{1.975}{R_e} \left(\log_e \left(\left(\frac{k}{3.93D} \right)^{1.092} + \left(\frac{7.627}{R_e + 395.9} \right) \right) \right) \right) \right) \right)^{-2} \quad (35)$$

Information on adaptive neuro-fuzzy inference system and mathematically exact alternative (Özger and Yıldırım, 2009a; 2009b) and other applications can be found in Chen (1985), Jang (1993), Hong *et al.* (2002); Jin (2003); Von Bernuth and Wilson (1989); Von Bernuth (1990); Yıldırım(2009); Xiande *et al.* (2011); Winning and Coole (2013); Wikipedia (2014); Salmasi *et al.* (2012); Samadianfard (2012); Papaevangelou *et al.*(2010); Mckeen *et al.*, (2004; 2005); Čojbašića. and Brkić (2013, 2016, 2017) and Çoban (2012). Heydari *et al.* (2015) utilized surface response for F_f calculation, and its accuracy was found to be limited to a certain range. Further information on F_f can be found in Petkovic *et al.* (2013a and b), Li *et al.* (2013), Vatankhah (2014); Mustafa *et al.* (2014); Kroll *et al.*(2014); Samadianfard *et al.* (2014), Alabi and Williamson (2015), Besarati *et al.* (2015), Brikic (2014; 2016); Dejan and Carko (2016); Taler (2016), Offor and Alabi (2016a and b) and Ismail *et al.* (2018).

Essential of accurate values F_f in the selection of pipe size (water distribution systems), estimation of flows and headloss in pipes, liquid and aqueous solutions transportation analysis and in the design of potable water supply scheme are well known. Also, there are various researches and publications on calculation of accurate F_f in the pipe as well as documentations on F_{ff} for F_f computations, but update and accuracies of these F_{ff} are rare. Advancement in technology and development of the high-speed computer have made computation easy and simple, which indicates that there is the need to document F_{ff} for exact F_f calculation and provide a performance assessment of each of these F_{ff} . The principal aim of this study is to provide F_{ff} for F_f calculation and performance assessment of each of these F_{ff} with particular attention to accuracy using statistical techniques with the aim of providing error-free explicit F_{ff} .

MATERIALS AND METHOD

F_{ff} which is a function of Reynolds number (R_e) and relative roughness (R_r) were obtained from archive with the aim to update the readers and conduct performance evaluation.

Colebrook – White's formula and these F_{ff} were used to compute different F_f for $4 \times 10^3 < R_e < 1.704 \times 10^8$ and $1.0 \times 10^{-7} < R_r < 0.052$ employing Microsoft Excel Solver. Microsoft Excel solver was selected based on availability (at no additional cost) and accuracy in numerical solutions. Accuracies of these F_{ff} were evaluated using relative error; model of selection (MSC) and the Akaike Information Criterion (AIC). Procedure used in Microsoft Excel Solver can be summarized as follows (Oke *et al.*, 2014a and b, 2015a, b and c):

- Excel solver was added in the Microsoft Excel;
- Target; operation and changing cells were set based on square of difference

$$\left[\sum_{t=1}^n \lambda_t - \sum_{t=1}^n R_e \left(\frac{k}{D} \right) \right]^2 = 0 ; \text{ and}$$

- The Solver was allowed to iterate at 200 iterations with 0.005 tolerance (Figure 1).

Relative error (R_{Err}) was determined using equation (48) as follows:

$$R_{Err} = \sum_{i=1}^N \left(100 \left(\frac{Y_{expect} - Y_{cali}}{Y_{expect}} \right) \right) \quad (48)$$

Where; Y_{expect} is the F_f from Colebrook – White's formula, and Y_{cali} is the calculated F_f from other friction factor formulae.

Akaike Information Criterion: Information Criterion of Akaike (1976) allows a direct comparison of different models with a different number of parameters (Romoe *et al.*, 2002). It represents the information content of a given set of parameters by relating the coefficient of determination to the number of parameters that were required to establish the fit. The Akaike Information Criterion (AIC) was determined as follows:

$$AIC = N \left(\ln \sum_{i=1}^n (Y_{expect} - Y_{cali})^2 \right) + 2p \quad (49)$$

where; p is the total number of fixed parameters to be computed in the equation ($p = 3$); N is the total number of F_f computed ($N = 5240$).

MSC can be computed using equation (50) as follows (Babatola *et al.*, 2008; Oke, 2007):

$$MSC = \ln \frac{\sum_{i=1}^n (Y_{expect} - \bar{Y}_{expect})^2}{\sum_{i=1}^n (Y_{expect} - Y_{cali})^2} - \frac{2p}{N} \quad (50)$$

RESULTS AND DISCUSSION

Results of the study were presented in the following categories: growth and patterns of F_{ff} , accuracies of the F_{ff} .

Growth and Pattern of F_{ff} : There are 47 F_{ff} that can be used for estimation of F_f in analysis of pipe systems between 1936 and 2017. Figure 2 (a and b) presents the patterns of the growth of these F_{ff} between 1936 and 2017. The F_{ff} can be grouped into four categories of first generation F_{ff} (1930 – 1960); second generation F_{ff} (1961 to 1990); third generation F_{ff} (1991 to 2008) and recent F_{ff} (2009 to 2017). The earliest F_{ff} for pipe systems analysis related Reynolds number and relative roughness and F_f was published in 1937. The number of F_{ff} has slowly grown in the long period from 1937 to 1960. The number was 4 out of 47. The number of F_{ff} went up significantly between 1970 and 1980. It rocketed between 1980 and 2008. This indicates that F_{ff} for pipe systems has become a hot topic worldwide, because of high rate increase of related literatures and human beings urgent necessary for energy consumption reduction, effective fluid delivery and environmental pollution control. The first generation F_{ff} were Colebrook- White formulae (1937); Moody (1944), and Altshul (1952). These three formulae are implicit and complex at a certain degree difficult to use, but formed foundation and bedrock for other F_{ff} . The second generation formulae are Wood (1966); Barr (1972 and 1981); Haaland (1983); Swamee and Jain (1976); Serghide (1984), Tsal(1989), Zigrang and Sylester(1982); Churchill (1973 and 1977), Jain (1976), Chen (1979), Eck (1973), Tsal (1989) and Round (1980). These second generation's F_{ff} are explicit formulae, which are with more than two variables. These second generation formulae look little more complex than the first generation formulae, but explicit formulae which provide solutions to the implicit formula. This can be attributed to availability of computer, which aid computations and development of accurate explicit formulae numerically through iterations. The third generation F_{ff} are Vatankhah and Kouchakzadeh (2008); Buzzelli (2008); Manadilli (1997), Romeo *et al.* (2002); Sonnad and Goudar (2004 and 2006). Recent F_{ff} are Avci and Kargoz(2009); Evanleids *et al.* (2010), Brkic (2011; 2012), Danish *et al.* (2011); Fang *et al.*, (2011),Ghanbari *et al.* (2011), Shaikh *et al.*(2015), Offor and Alabi (2016a and b), Lukman and Oke (2017), Ismail *et al.* (2017), Lukman *et al.* (2017a and b). These F_{ff} (third generation and recent) are similar in form of variables and levels of parameters, but different by numerical values. These similarity and differences can be attributed to advancement in computer and technology as well as availability new numerical solutions. The number of F_{ff} grew from 1 in 1937 to 47 in 2017, which fitted into power model ($R = 0.9724$ with $R^2 = 0.9456$) and an exponential model of $R = 0.9719$ with $R^2 = 0.9446$ presented good relationship (Figure 3a). A significant correlation between the number of formulae and the year was observed with a high coefficient of determination ($R^2 = 0.9582$). Both the power and the exponential curve fitting indicated that there was a high growth rate for annual F_{ff} . The power and exponential fitting curves indicated that there are more researches on F_{ff} for fluid (gas, water and wastewater treatment etc.) transport technology were found to be $C = 0.8854X^{0.7458}$ and $C = 1.9968Exp^{0.0368X}$ respectively, Where; C is the cumulative number of F_{ff} and X is the number of years with 1936 as the base year, with coefficient of determination (CD) of 0.8589 and 0.9582 and correlation coefficient (R) of 0.9268 and 0.9789 respectively. These values of CD and R revealed that there is are good correlation for power and exponential fitting. Based on the exponential model, the number of F_{ff} in 2018 is expected to be six times more than that in 2012. The average number of F_{ff} developed per year fluctuated slightly with an overall average of 0.365 per year. Figures 3a, b and c present growth pattern of F_{ff} in various sub groups. The average number of F_{ff} developed per year were 0.129; 0.451 0.333 and 0.777 for each of the generations (sub groups). There was a high average in the

recent years, which indicated that the breadth of F_{ff} distribution as well as the broad interest in F_f research from various research angles.

The growth pattern of F_{ff} in line with various generations are as follows:

- i. Exponential relationship are $C = 1.4324Exp^{0.1024X}$, $C = 0.610Exp^{0.1306X}$, $C = 1.3859Exp^{0.3055X}$ and $C = 0.420Exp^{0.1904X}$ with CD of 0.6067, 0.9526, 0.7808 and 0.8701 for first, second, third and recent generation F_{ff} respectively; and
- ii. Powerfunctionrelationship are $C = 1.2416X^{0.5519}$, $C = 0.0277X^{2.0685}$, $C = 0.0582X^{1.6635}$ and $C = 1.1029X^{1.2751}$ with CD of 0.8567, 0.9564, 0.9582 and 0.9064 for first, second, third and recent generation F_{ff} respectively.

The grown pattern of F_{ff} in the first generation neither fits exponential nor power based on lower values of CD. The grown pattern of the second generation of F_{ff} had CD of 0.9526 and 0.9564, indicated that grown pattern fits well into power relationship than another relationship. It implies that growing and researches on F_f were of higher geometric progression at the this second stage. This can be attributed to interest in fluid transport and availability of computers. The grown patterns of the third and fourth generation formulae were similar to that of second generation formulae, which are well expressed by power fitting relationship.

Classification according to the number of the authors revealed that F_{ff} with three or more authors accounted for 37.20%, F_{ff} with two authors accounted for 22.93% and F_{ff} with single author accounted 39.87%. There was an increase in the co-authors and collaboration in the recent years (12.90% to 35.69% for three or more authors and decreased from 3.22% to 2.40% for each of single and two authors), which indicated an awareness in F_{ff} as well as the broad interest in F_f researches from various angles. Grouping of F_{ff} based on the nature of the equation revealed that the equations are of two types: simple and multiple equations. Multiple equations accounted for 21.23% and simple equation accounted for 78.77%. These ratios indicated that the developed and F_{ff} in use gave rooms for making a choice of F_{ff} to be used. From these F_{ff} , the parameters were different from each other F_{ff} , but there are general for all these F_{ff} .

Statistical evaluations of the F_{ff} : Table 1 presents values of AIC, MSC, and relative error. Based on the statistical evaluations (AIC, MSC, and relative error) of the F_{ff} , the formulae can be grouped into five categories as follows:

- a. **Perfect F_{ff} .** These are the F_{ff} with a relative error less than 1.0%, with MSC greater than 6.64 and AIC less than -34327.16. The formulae are Barr (1972), Prandtl and Nikurdse, Swamee and Jain, Serghide, Zigrang and Sylvester, Romeo et al. (2002), Brkic (2011), Eck (1973), Fang *et al* (2011, Smooth and Rough), Shaikh *et al* (2015), Offor and Alabi (2016), Lukman *et al* (2017 a and b), Ismail *et al* (2017), Lukman and Oke (2017);

Highly accurate F_{ff} . These are the F_{ff} with a relative error greater than 1.0% but less than 3.0%. The formulae are Haaland ; Wood

- b. **Moderately accurate F_{ff} .** These are the F_f with a relative error greater than 5.0%, but less than 10.0%. The formula are Moody, Churchill (1973 and 1977), Jain, Chen (1979), Buzzelli (2008), Sonnad and Goudar (2004 and 2006), Swamee and Jain (b), Barr (1981), Ghanbar et al (2011), Manadilli, Evangleids et al (2010), Vatankhah and Kouchakzadeh, Romeo et al ;

c. **Low accurate F_{ff}** These are the F_f with a relative error greater than 10.0%, but less than 20.0%.

The formulae are Round (5.53%) and Tsal ;

- d. **Least accurate F_{ff} .** These are the F_f with a relative error greater than 20.0%. The formulae are Avci and Kargoz (2009), Danish *et al* (2011), and Fang *et al* (2011, smooth only).

CONCLUSION

Based on the statistical assessment of all F_{ff} , it can be concluded that:

- i. New generation F_{ff} are the best F_{ff} tools for estimating F_f in the pipeline problems based on the values of MSC, AIC, and relative error; and
- ii. there is the need to perform economics evaluation on these F_{ff} to ascertain their reliability.

The Role of Two-Dimensional Materials in Electromagnetic Interference Shielding

Rafael Vargas-Bernal

 <https://orcid.org/0000-0003-4865-4575>

Instituto Tecnológico Superior de Irapuato, Mexico

INTRODUCTION

The extensive use of electronic and wireless technologies has led to the need to develop materials that present high performance shielding against electromagnetic interference (EMI), which avoid pollution by electromagnetic waves that affect the operation and life time of electronic devices as well as the Human health (Song, 2017; Wang, 2017; Liu, 2019). Commonly, metallic materials are used in practical ways to increase the shielding effectiveness (SE) through an appropriately designed assembly process. Unfortunately, the high density of devices that require it and the poor environmental stability of metals have impeded their massive use. In addition, materials with light weight and good chemical stability are also required for applications in the automotive, aerospace and electronics industries.

Research in the area of materials engineering has introduced two-dimensional materials in the last decades as an alternative option to increase the efficiency of electromagnetic shielding. Two-dimensional materials are defined as crystalline materials of a single layer of two-dimensionally arranged allotropic atoms based on elements or compounds (two or more covalently bonded elements). In the following paragraphs, the fundamental role that these materials play in the future of electromagnetic shielding is introduced. The advent of two-dimensional materials in the area of electromagnetic interference will mitigate the harmful effects of excessive use of electronic and telecommunications devices through electromagnetic shielding for commercially, industrially and militarily used systems. In this way, the manufacture of electronic systems must include an electronic packaging that involves the application of two-dimensional materials used as electronic fillers in composite materials based on polymeric, ceramic or metallic matrices. From a commercial point of view, the integration of two-dimensional materials will provide a high added value to products that include more efficient electromagnetic shielding than that achieved with current technologies.

Carbon-based nanomaterials such as graphene and carbon nanotubes have recently been introduced to control electromagnetic interference or mitigate contamination by electromagnetic radiation, and because they offer characteristics such as low density, high electrical conductivity and good chemical resistance (Dhakate, 2015; Xu, 2018; Zhao, 2018a). Of these nanomaterials, graphene is a two-dimensional carbon material with a higher electrical conductivity than carbon nanotubes, which further increases the shielding effectiveness (Bhattacharjee, 2017; Liu, 2019). To use the multifunctional properties of these nanomaterials in practical applications, it is necessary to implement nanocomposites that contain them regularly embedded in polymer matrices. Two-dimensional materials must be incorporated in small quantities and form efficient conductive networks within the composite material that will be formed by exploiting their high intrinsic electrical conductivity, large aspect ratio, good dispersion, and homogeneous distribution.

Carbonitrides and/or carbides based on transition metals called MXenes represent other highly conductive two-dimensional nanomaterials that can be used to provide electromagnetic interference

DOI: 10.4018/978-1-7998-3479-3.ch086

shielding when incorporated into polymeric materials such as polystyrene (Sun, 2017a; Cao, 2018; Fan, 2018; Liu, 2018; Raagulan, 2018; Cao, 2019). Additionally, two-dimensional materials are attractive for their light weight, flexibility, hydrophobicity, good durability, strong absorption capacity, and shielding against electromagnetic interference up to 70 dB that are not offered by bulk materials. These two-dimensional materials must be used functionalized or used in combination with metals (Liu, 2019) or ceramics (Sharif, 2017; Jin, 2018; Ru, 2018) embedded in polymer matrices based on thermoplastics, thermosets or conductive polymers. Other two-dimensional materials that exhibit shielding properties are black phosphorus (BP), transition metal dichalcogenides (MoS_2), and carbon nitride (C_3N_4). Multiple two-dimensional materials with van der Waals structure or heterostructures have also been used (Zhao, 2018b).

The purpose of this chapter is to describe the impact that two-dimensional materials (or 2D materials) are having on the development of materials used for electromagnetic interference shielding, particularly the impulse of materials such as graphene and MXenes. The advances in the last decade are analyzed and alternatives are proposed that will come in the next decades. The shielding mechanisms presented by two-dimensional materials are analyzed in detail and the specific applications in which these materials can be used are presented.

BACKGROUND

In this section, the chapter describes the basic concepts associated with the technical principles on which the shielding to electromagnetic interference is based. The overly exhaustive use of technologies operating in the high-frequency range has led to a new type of pollution called electromagnetic interference (EMI) (Bhattacharjee, 2017). Any device that transmit, distributes or uses electrical energy produces electromagnetic interference, which can have a damaging impact on the performance of other devices or the surrounding environment. This problem has been accentuated more because the electronic devices have reduced the size of their components and operate at much faster speeds, which can encourage the malfunction and/or degradation of the devices. This electromagnetic pollution has not been completely restricted, since it is also affecting the human being as well as the surrounding environment due to the absence of adequate shielding. The largest problems of electromagnetic interference are observed in applications where large amounts of data are used such as electronic equipment, industrial equipment and communication systems (Cao, 2019). Systems present two types of interference: electronics and radiation sources. Electromagnetic shielding involves the blocking of electromagnetic radiation so that it does not pass through a blocking or shielding material (Dhatake, 2015). Electromagnetic interference shielding is used in applications such as the radar absorption, aviation, portable electronic devices, camouflage materials, automotive systems, aerospace systems, and military systems (Raagulan, 2018). Materials that are capable of absorbing and attenuating incident microwaves used in military applications are called microwave absorbing materials (Wang, 2018). Since the late 1940s, many researchers around the world have turned their attention to studying microwave absorbing materials with two specific properties: lightweight and high absorption efficiency. In addition, these materials must have matching properties of optimal impedance (to ensure that the electromagnetic waves enter the material) and high attenuation constant (to consume the energy of the electromagnetic wave). An excellent electromagnetic wave absorbing material must be capable of absorbing waves over a wide range of frequencies, having a low density, lightweight, large surface area, and good thermal and chemical stability (Prasad, 2018).

An option to respond to electromagnetic interference (EMI) is to design and manufacture materials that can reduce or restrict the undesired effect of these electromagnetic waves (Bhattacharjee, 2017). The desired properties for these materials include a low reflection loss, a broad attenuation band, lightweight and economic viability. A successful electromagnetic shielding material must both decrease unwanted emissions and defend the device or human being from these signals. The primary function of electromagnetic shielding is to reflect the electromagnetic radiation using the charge carriers of the materials that interact with electromagnetic fields, so it is expected that the material used in the shield has a semiconductor or metallic electrical behavior. As a second function, it is required that the electrical and magnetic dipoles of the material absorb the electromagnetic radiation during the interaction with the electromagnetic fields. And, as a third function of the shielding material, within its structure there is the possibility that multiple internal reflections are generated, which scatter or absorb the electromagnetic waves due to the presence of dispersion centers or defects. The material that commonly perform this function are metals, but in the case of smaller devices their inclusion increases their weight and make them susceptible to chemical corrosion. In addition, metals are difficult and expensive to process and have low specific shielding capabilities (Dhakate, 2015). As alternative materials, polymer matrix composites that make use of conductive fillers and/or materials with magnetic properties have been proposed to replace metals, which have performed similarly but not as effectively until the advent of the two-dimensional materials. The shielding effectiveness of the polymer composite depends on the intrinsic electrical conductivity, dielectric constant, magnetic permeability, aspect ratio, and content of the conductive filler. The main disadvantage of nanocomposites is its tendency to reflect electromagnetic radiation instead of absorbing it. Another attractive option has been the use of conductive polymers that have finite electrical conductivity and no transparency to microwaves.

The shielding efficiency or shielding effectiveness (SE) of a material determines its ability to attenuate the incident electromagnetic radiation and is expressed in decibels (dB) (Bhattacharjee, 2017). The greater the shielding effectiveness, the smaller the amount of energy that passes through it. The shielding is most effective when most of the electromagnetic radiation is either reflected or absorbed by the shield. In the case of reflection, its performance is governed by the surface reflection of the free charge carriers found on the surface of the material, as well as by the multiple internal reflections produced by the adjacent electrically conductive layers. On the other hand, the absorption of the electromagnetic radiation in the shielding material is governed by different loss mechanisms related to the electric and magnetic polarization processes within the material. Therefore, the total shielding effectiveness (SE_T) can be expressed mathematically as the sum of the shielding effectiveness to reflection (SE_R), to multiple reflections (SE_{MR}) and to absorption (SE_A):

$$SE_T = SE_R + SE_{MR} + SE_A = \log_{10} \left(\frac{P_i}{P_t} \right) \quad (1)$$

where P_i and P_t represents the incident and transmitted power radiation, respectively. Because the transmitted power is expected to be much smaller than the incident power, the value of the effectiveness is negative, and the higher this value is, the better the electromagnetic shielding obtained. Regularly, the losses associated with multiple internal reflections can be ignored when the effectiveness of the shielding material is greater than -10 dB (Dhakate, 2015). Effectiveness by reflection can be determined mathematically by the equation:

$$SE_R = -10 \log \left(\frac{\sigma_T}{16\omega\epsilon_0\mu_r} \right) \quad (2)$$

where σ_T is the total electrical conductivity of the shielding material, ω is the angular frequency of the electromagnetic radiation, ϵ_0 is the electrical permittivity of the vacuum and μ_r is the relative permeability of the shielding material. From Equation 2, it can be deduced that the reflection is directly proportional to the ratio of the electrical conductivity and magnetic permeability of the material and inversely proportional to the electromagnetic signal's frequency. Effectiveness by absorption can be determined mathematically by the equation:

$$SE_A = -8.68t \sqrt{\frac{\sigma_T \omega \mu_r}{2}} \quad (3)$$

where t is the thickness of the shielding material. From Equation 3, it can be deduced that the absorption is directly proportional to the thickness, electrical conductivity and magnetic permeability of the shielding material as well as to the angular frequency of the incident radiation. In addition, according to Equation 3, the thicker the shielding material is, the greater the absorption of the applied electromagnetic wave. Because the total electrical conductivity can be expressed as

$$\sigma_T = \omega\epsilon_0\epsilon'' \quad (4)$$

where

$$\epsilon_T = \epsilon' - j\epsilon'' \quad (5)$$

Therefore, the electrical conductivity of the shielding material depends on its complex electrical permittivity. Further studies have shown that the shielding mechanism depends exclusively on the losses, which are improved by increasing the transmission routes of the incident waves that involve only the values of relative permittivity and permeability of the shielding material. In this way, the design and manufacture of materials that offer better routes for reflection, multiple reflections and absorption, which reach to dissipate the effect of electromagnetic radiation, is a priority so that these can be applied as shielding materials. Physicochemical properties such as electrical conductivity, electromagnetic polarization, crystalline structure, aspect ratio, thickness, type of material and fillers influence in the efficiency of specific electromagnetic shielding (Raagulan, 2018). Multiple internal reflections are favored by controlling thickness, skin depth, absorption of electric and magnetic dipoles, use of multi-layer materials and scattering centers. The electromagnetic reflection mechanism is favored with a high electrical conductivity. The new materials used as electromagnetic shielding materials must then be able to tune their performance by controlling their thickness and improving the mechanical properties to be able to adapt as coatings. The main mechanisms that occur in materials due to the incidence of electromagnetic waves on them are illustrated in Figure 1.

Figure 1. Mechanisms of interaction of electromagnetic waves with materials

FOCUS OF THE ARTICLE

In this section, the chapter describes the basic concepts associated with two-dimensional materials and the relevant properties that these materials possess to develop electromagnetic shielding. Two-dimensional materials have been considered as emerging materials in innumerable applications thanks to their unique electrical, optical, thermal, magnetic, and mechanical properties. The main types of materials that can be used in electromagnetic shielding are dielectric loss materials, magnetic loss materials and electromagnetic composites. The main morphologies based on nanomaterials for shielding that have been used so far are nanoparticles, nanowires, nanobars, nanotubes and nanosheets (Cao, 2019). Among the promising two-dimensional materials for electromagnetic interference shielding are materials such as graphene, MXenes, transition metal dichalcogenides, black phosphorus and graphitic carbon nitride ($g\text{-C}_3\text{N}_4$). In addition to electromagnetic interference shielding, two-dimensional materials have potential to be used in electromagnetic fields, microwave absorption, information security, electromagnetic protection, and electromagnetic wave imaging. With the introduction of two-dimensional materials, researchers around the world are working on the preferential assembly of these materials in multilayered or sandwich structure architectures. These architectures offer better electromagnetic shielding properties, lower percolation threshold, flexibility and impact toughness, which are other very important qualities during the manufacture and operation of these materials (Bhattacharjee, 2017). The electronic behavior of two-dimensional materials during electromagnetic shielding is strongly related to their crystalline structure and their electronic states. Each two-different material has a different electronic structure, energy-band structure, density of states, electronic spin, charge difference density, phonon vibration, etc. very different. The electrical conductivity can be increased by decreasing the band gap, while the lattice vibration can reduce it when producing carrier scattering. The defects and groups on the materials modify the charge density giving rise to dipoles which generate relaxation if the electromagnetic field of the interference is alternating. The magnetic spin dipole comes from the location and position

of electrons which can move due to the presence of electromagnetic radiation. The electromagnetic response of two-dimensional materials is derived from their electron transport, dipole relaxation, magnetic resonance and Eddy current (Cao, 2019). For a shielding material (common in a two-dimensional material) to absorb electromagnetic radiation, it must have a dielectric constant as close as possible to that of air (Dhakate, 2015).

MXenes are a unique family of two-dimensional materials based on transition metal carbides and/or nitrides with the chemical formula $M_{n+1}X_nT_x$, where M is a transition metal (Ti, Zr, V, Nb, Ta or Mo) and X is a chalcogen (S or O) (Bhattacharjee, 2017; Anasori, 2019). Because these materials are obtained in aqueous media during their synthesis, they can be terminated with different surface moieties (T_x), such as a mixture of OH^- , O^{2-} , and F^- . In addition, these materials have metallic conductivity, good mechanical properties, and are hydrophilic, which makes them attractive to form polymer composite materials (Shahzad, 2016). Polymer-MXene composites have an improved tensile strength and good electrical conductivity even at low percolation thresholds. The properties described above make these materials an emerging alternative to apply in shielding electromagnetic interference. MXene materials perform better on electromagnetic shielding than many other metals and carbon-based materials (Sun, 2017a). In the MXenes group, the $\text{Ti}_3\text{C}_2\text{T}_x$ has been the most explored and has an electrical conductivity of 650 000 S/m. The advantages of MXenes over other shielding materials are its laminated morphology and its unique physical and chemical properties.

Carbon-based materials have always shown the potential to absorb microwaves in almost all their morphologies (black carbon, carbon nanotubes, carbon fibers and graphene), but graphene stands out among them (Sharon, 2015; Wang, 2018). Graphene sheets are two-dimensional layers of an atom thick with carbon atoms with sp^2 bonds (Dhakate, 2015). Graphene exhibits high electrical conductivity, large surface area, excessively low density, thin thickness and fascinating advantages for developing radar absorbing materials or as shielding materials for electromagnetic interference. The advantages of composite materials based on graphene are its low cost, high aspect ratio, and lightweight. Due to its low density and resistance to corrosion, graphene and reduced graphene oxide, also two-dimensional materials, have recently been proposed as alternative materials to develop electromagnetic shielding. The presence of functional groups and defects in graphene can produce asymmetric charge density differences producing electrical dipoles and if these are subjected to alternating electromagnetic fields, the dipoles will break and generate orientation rotation, and convert the electromagnetic energy into thermal energy during the relaxation (Cao, 2019). Pure graphene cannot satisfy the impedance matching condition required for microwave absorption due to its high electrical conductivity and electromagnetic parameters (Hao, 2018). In order to use graphene in microwave absorbing materials, it is necessary to design functional composite materials with other active second phases to reduce their electrical conductivity and to achieve large-scale production. Although the interfacial interactions in these composites improve the microwave absorption properties, the second phases, usually based on metals and metal oxides, give rise to materials with high densities, which makes them impractical.

Transition metal dichalcogenides (TMDs) monolayers are an option of two-dimensional materials that exhibit a semiconductor behavior with chemical formula MX_2 , where M is a transition metal atom (Mo, W, etc.) and X a chalcogen atom (S, Se, or Te). These materials are structured so that a layer of transition metal atoms is sandwiched between two layers of chalcogen atoms (Kolobov, 2016; Wang, 2018). Among the electronic properties that dichalcogenides present are a direct band gap, its structure has no inversion center which increases the degree of freedom of charge carriers, and a strong spin-orbit coupling leads to a splitting in hundreds of meV the valence band and in a few meV to the conduction band, which allows to control the electron spin minutely. Within its large family, molybdenum disulfide

(MoS₂) exhibits high electron mobility, tunable band structure and different morphologies that are required for a good microwave absorbing performance.

The two-dimensional version of phosphorous like graphene is known as phosphorous or black phosphorus. This material unlike graphene has a band gap that can be tuned by changing the number of layers used (0.3 eV for its bulk version and 1.88 eV in a monolayer). The individual layers are held together by Van der Waals forces. Their monolayers show a structure of the quadrangular pyramid due to the bonds between their atoms with different angles (Hao, 2018).

SOLUTIONS AND RECOMMENDATIONS

In this section, the chapter describes some practical examples where two-dimensional materials have been successfully applied in the shielding to electromagnetic interference of electromagnetic signals in various technological sectors. Two-dimensional materials (2D materials) are attractive for numerous applications due to their unusual physical and chemical properties derived from their strong interaction of electrons confined in a plane, and the effect of significant and anisotropic quantum confinement (Hu, 2018). In the cases of graphene and MXenes, their electromagnetic shielding properties are attributed to their special electrical behavior, large specific surface area, and low mass density. The inherent advantages of two-dimensional materials to be used as microwave attenuating materials are: 1) very large specific surface area and numerous interfaces for interfacial polarization as well as for the reflection and scattering of electromagnetic waves, 2) its ultra-small thickness that does not allow the penetration and dissipation of electromagnetic waves leads to multiple internal reflections and the dissipation of electromagnetic energy through topologies such as layer-by-layer assemblies, core-shell particles and porous foams, and 3) good processability that makes them easily integrable to multifunctional composites with multiple modes of attenuation of electromagnetic energy. In addition, these materials behave as microwave reflectors and absorbers, act as impedance regulators and provide structural support for good impedance matching and to establish the optimal structure (Hu, 2018). The different mechanisms present in two-dimensional materials to increase the shielding effectiveness (SE) are shown in Figure 2.

The first two-dimensional carbide (Ti₃C₂) was introduced in 2011 and from then until now numerous two-dimensional carbides, nitrides and carbonitrides called MXenes have been discovered or isolated, so that their technological development and scientific research are still in their infancy (Li, 2018). Microwave attenuation capacity was demonstrated for Ti₃C₂ nanosheet and paraffin-based composites in the 2 to 18 GHz range with a thickness of 2 mm presenting a reflection loss of 40 dB (Feng, 2018). The absorption mechanism is due to the high dielectric loss and strong multiple internal reflections among layers of the MXene.

Ti₃C₂T_x films with thickness in the range of 1 to 45 microns showed excellent electrical conductivity and electromagnetic interference shielding (Shahzad, 2016). The 45-micron thick film showed an effectiveness of 92 dB (more than 50 dB for a 2.5-micron film). According to the authors of the article, these materials present the highest effectiveness values of any known synthetic material of similar thickness. Its performance is derived from excellent electrical conductivity (4600 Siemens per centimeter) and multiple internal reflections in the case of free-standing films. The main electromagnetic shielding mechanism for the composite material was absorption instead of reflection in the case of pristine MXene. In this study they analyzed the electromagnetic shielding performance of MXene films based on Ti₃C₂T_x, Mo₂TiC₂T_x and Mo₂Ti₂C₃T_x. The shielding capacity is maintained (57 dB) even when the MXene is added to sodium alginate (SA) to create polymer composite films. SA is a linear polysaccharide copolymer

Figure 2. Mechanisms for electromagnetic interference shielding presented in two-dimensional materials

derived from marine algae that is abundant biomaterial, non-harmful to the environment, mechanically robust and with functional groups containing oxygen (OH^- , COO^- , and O^{2-}) that facilitate the formation of hydrogen bonds with functional groups of MXenes.

Composite materials based on cellulose nanofiber (CNF) and extremely thin and highly flexible $\text{Ti}_3\text{C}_2\text{T}_x$ MXene with a nacre-like lamellar structure were manufactured using a self-assembly process induced by vacuum filtration (Cao, 2018). For a film with a thickness of 47-microns, high tensile strength (up to 135.4 MPa), fracture strain (up to 16.7%), folding endurance (up to 14 260 times), high electrical conductivity (up to 739.4 S/m) and efficiency to the excellent specific electromagnetic shielding (up to 2647 dBcm²/g). In these composite materials, the main shielding mechanism is electromagnetic absorption and in the case of pristine MXene is electromagnetic reflection. The function of cellulose nanofiber is to provide high mechanical strength, great flexibility and reduce the number of insulating contacts between the conductive nanosheets of the two-dimensional material. This composite material can develop shielding for electromagnetic interference in applications such as flexible wearable devices, weapon equipment, and robot junctions.

Electrostatic assemblies using negative $\text{Ti}_3\text{C}_2\text{T}_x$ MXene nanosheets on positive polystyrene microspheres using compression molding with a low percolation threshold of 0.26 vol% presented an electrical conductivity of 1081 S/m and a shielding effectiveness greater than 54 dB or for a 1.90 vol% with an effectiveness of 62 dB were implemented (Sun, 2017a). Pristine MXene presents electromagnetic shielding due to reflection, while the composite material presents shielding due to electromagnetic absorption. The use of conductive polymer nanocomposites is favored by its excellent processability and its versatility of tuning properties over wide ranges. Their properties depend on their intrinsic conductivity, aspect ratio, dispersion, and distribution of conductive fillers. An excessive increase in the amount of filler used in the composite material is not feasible because its processing is difficult, and a catastrophic deterioration in its mechanical properties as coating occurs.

In the search for multifunctional materials, a material formed by the combination of Ti_3SiC_2 MXene and the composite formed between silicon carbide and carbon fibers (SiC/C) has been synthesized (Fan, 2018). Composite SiC/C for thermostructural applications has low density, high thermal shock resistance, good thermal stability, and excellent mechanical properties at high temperatures. Ti_3SiC_2 presents a high electrical conductivity and a shielding effectiveness (SE) against electromagnetic interference of 35 to 54 dB in the frequency range of 8.2 to 18 GHz (X-Band). The electromagnetic shielding mechanism for these materials is absorption, instead of reflection, which is presented in pristine MXene and composite SiC/C.

Most composites based on polymers and two-dimensional materials have a “brick and mortar” structure. Composites based on $\text{Ti}_3\text{C}_2\text{T}_x$ and poly(3,4-ethylenedioxythiophene)-poly(styrenesulfonate) (PEDOT-PSS) with a weight ratio of 7:1 with a thickness of 11.1 μm showed a shielding effectiveness of 42.1 dB (Liu, 2018). In addition, this film showed lightweight, a tensile strength of 13.71 MPa, an electrical conductivity of 340.5 S/cm and a specific shielding efficiency of 19,497.8 dBcm²/g. The main electromagnetic shielding mechanism in this material was absorption, instead of reflection, that it is presented in pristine MXene.

Composite materials based on $\text{Ti}_3\text{C}_2\text{T}_x$ MXene and non-woven carbon fabric offer lightweight and flexible materials with shielding effectiveness of 43.2 dB and specific shielding efficiency of 8534.7 dBcm²/g at 2.3 GHz (Raagulan, 2018). The main applications where these materials can be used are aviation, portable electronics, radars, aerospace, and military. The mechanism associated with electromagnetic interference shielding in this case is associated with both electromagnetic reflection and absorption.

Hybrid aerogels based on two-dimensional materials have been proposed as three-dimensional materials for electromagnetic interference shielding (Zhao, 2018b). The proposed two-dimensional materials

were $\text{Ti}_3\text{C}_2\text{T}_x$ MXene and reduced graphene oxide (rGO). The resulting material had an electrical conductivity of 695.9 S/m and a shielding effectiveness of more than 50 dB in the X-band, with a content of 0.74 vol% of MXene. The main electromagnetic shielding mechanism for the composite material was absorption, instead of reflection, in the case of the pristine MXene.

$\text{Ti}_3\text{C}_2\text{T}_x/\text{Ni}_{0.5}\text{Zn}_{0.5}\text{Fe}_2\text{O}_4$ composites obtained by in situ co-precipitation with a 5 wt% $\text{Ti}_3\text{C}_2\text{T}_x$ presented a shielding effectiveness of 42.5 dB in the K-Band (12–15 GHz) (Li, 2017). The electromagnetic wave absorption mechanism is complex, since it involves magnetic loss, dielectric loss, conductivity loss, multiple reflections, and scattering. These sub-mechanisms are difficult to achieve through a single material; therefore, hybrid materials provide an option of technological development to increase or guarantee a true shield against electromagnetic interference.

Composite materials based on molybdenum disulfide (MoS_2) nanostructures with a diameter of 40 to 60 nm and carbonyl iron@ SiO_2 particles were synthesized to form a microwave absorbing material (Wang, 2018). Materials of 1.6 mm thickness with 15 wt% of MoS_2 showed a minimum reflection loss of -28 dB at 12.4 GHz. This type of materials, in addition to having an easy synthesis process, presents a good absorption performance with thin thickness and mechanical strength at high temperatures. Novel materials based on molybdenum disulfide (MoS_2) have been designed using different reinforcements: 1) nickel nanoparticles, 2) carbon nanotubes using a one-dimensional architecture, and 3) carbon nanotubes using layers of three-dimensional carbon nanotubes (Sun, 2017b). For this group of materials, their shielding effectiveness (SE) were 19.7 dB at 2.92 GHz, 47.9 dB at 5.60 GHz, and 69.2 dB at 4.88 GHz, respectively. The control of interfacial contacts in the materials produced makes van der Waals heterostructures an alternative strategy to develop microwave attenuation properties. The main mechanism of electromagnetic shielding involved in reducing interference for this type of materials is based on electromagnetic absorption.

Electrically conductive networks based on hybrid materials formed by the stacking of layers of reduced graphene oxide (rGO) and molybdenum disulfide (MoS_2) (20 wt%) present electromagnetic absorption with a shielding effectiveness of 10 to 60 dB at a thickness of 2.5 mm (Xie, 2016). The main mechanism of electromagnetic shielding is electromagnetic absorption. Nanocomposites based on molybdenum disulfide (MoS_2), reduced graphene oxide (rGO) and magnetite nanoparticles (Fe_3O_4) were synthesized by hydrothermal process for electromagnetic shielding applications (Prasad, 2018). A shielding effectiveness of 8.27 dB, improved magnetic loss and matching impedance were achieved for the range of 8 to 12 GHz, thanks to dielectric loss by molybdenum disulfide and graphene, as well as magnetic loss by magnetite. In this way, the combination of material forming hybrid materials can provide better electromagnetic interference shielding.

An ultra-lightweight composite aerogel based on reduced graphene oxide (rGO) and black phosphorus (BP) or phosphorene was manufactured using a self-assembly process (Hao, 2018). This material exhibited a reflection loss of 46.9 dB for a thickness of 2.53 mm in a wide absorption band of 6.1 GHz, and which can be used as an ultralight microwave absorber. The shielding mechanism is mainly dominated by electromagnetic absorption produced by multiple internal reflections within the hybrid material. The structure between these two-dimensional materials formed four kinds of interconnected interfaces such as wrapping, wearing, bridging and weak linking.

Flexible polydimethylsiloxane (PDMS)-graphene composite foam using a chemical vapor deposition technique achieved a specific shielding effectiveness of 333 dBcm^3/g with 0.8 wt% graphene loading in the X-band frequency range (Dhakate, 2015). The effectiveness value is higher than that obtained for solid copper of 10 dBcm^3/g or 33.1 dBcm^3/g para PDMS-carbon nanotube composites with 7 wt% of carbon nanotubes. In this composite material, electromagnetic shielding is due to electromagnetic

absorption and multiple internal reflections produced within the foam. These types of materials can be used in applications such as aircraft, spacecraft, automobiles and portable electronics. Composites based on poly(dimethylsiloxane) and graphene were synthesized using 3.07 wt% of graphene and presented an electrical conductivity of 103 S/m and shield effectiveness of 54 dB in the X-band (Xu, 2018). These materials behave flexible, so they can be used in wearable devices and as shelters to protect against electromagnetic interference. Another option for composite materials for electromagnetic shielding based on polydimethylsiloxane (PDMS) was reinforced by reduced graphene oxide (rGO) and single-walled carbon nanotubes (SWCNTs) (Zhao, 2018a). These materials reached, in addition to being flexible and having lightweight, an electrical conductivity of 1.2 S/cm and a shielding effectiveness of 31 dB over the range of the X-band.

Hybrid materials have also been synthesized to improve the shielding effectiveness based on silicone rubber vinyl methyl silicone (VMQ), graphene nanoplate, magnetite (Fe_3O_4) @ barium titanate (BaTiO_3) (GMBT) nanoparticles and multiple wall nanotubes (MWCNTs) (Jin, 2018). The shielding effectiveness for this material was in the range of 26.7 to 33.3 dB (attenuation greater than 99.8%) with a load of 16.1 wt% total filler (GMBT: MWCNTs = 5:1). The shielding mechanism is mainly dominated by the absorption of electromagnetic radiation, thanks to the multiple internal reflections within the hybrid material.

Hybrid nanocomposites based on poly(methyl methacrylate), graphene and magnetite (Fe_3O_4) have been used as shielding material for electromagnetic interference (Sharif, 2017). Nanocomposites with a 0.3 vol% rGO obtained an electrical conductivity of 91.2 S/m and presented a shielding effectiveness of 63.2 dB for a 2.9 mm film. In this composite material, the main mechanism for allowing electromagnetic shielding is the electromagnetic absorption produced by the multiple internal reflections presented.

Aerogels based on reduced graphene oxide (rGO) and silver nanowires (AGNWs) were synthesized, and these reaching a shielding effectiveness of 45.2 dB and a mechanical strength of 42 KPa (Liu, 2019). They are ideal for applications that require mechanical robustness and shielding against electromagnetic interference. The shielding mechanism is mainly dominated by the absorption of electromagnetic radiation, thanks to the multiple internal reflections within the hybrid material. In this structure, the one-dimensional silver nanowires attached to the graphene sheets act as a bridge among the sheets to facilitate the formation of an electron-hopping conductive network.

Electromagnetic shielding for harsh environments requires the use of ceramic composites with good electrical conductivity, lightweight, and high mechanical strength. A composite based on mullite and reduced graphene oxide (rGO) has been sintered by plasma at 1200 °C using $\gamma\text{-Al}_2\text{O}_3\text{@SiO}_2$ powder as a precursor (Ru, 2018). This material achieved a shielding effectiveness greater than 32 dB and an electrical conductivity of 696 S/m using only 0.89 vol% rGO to operate in the K-band without losing its mechanical properties. The mechanism of multiple internal reflections is the main responsible for electromagnetic shielding. This material can be used in applications where high mechanical stresses and high temperatures are presented.

Several types of dielectric spacers based on graphene, graphene oxide and polymers that result in materials with electrical loss and magnetic loss have provided improvements in shielding effectiveness (SE) (Song, 2017). These materials presented a shielding effectiveness higher than 20 dB in the X-band thanks to the frequency selectivity associated with them. The main mechanism of electromagnetic shielding is based on multiple internal reflections.

Sandwiches formed from stacked films with multiple layers based on: 1) graphene oxide (GO) doped with nitrogen, and 2) copper phthalocyanine, have been synthesized as materials for electromagnetic shielding (Wang, 2017). These materials present a shielding effectiveness of up to 55.2 dB for a thick-

Figure 3. Shielding effectiveness for different two-dimensional materials

ness of 0.47 mm and an electrical conductivity of 3.64×10^3 S/m. The mechanism of absorption is the main responsible for electromagnetic shielding.

A comparison of the performance of different types of materials based on two-dimensional materials to improve shielding effectiveness is illustrated in Figure 3.

FUTURE RESEARCH DIRECTIONS

The introduction of two-dimensional materials not only seeks to effectively shield electromagnetic interference but also to reduce the weight of cars and airplanes to increase energy efficiency. Future materials used in the shielding of electromagnetic interference should exploit the quantum confinement of electrons (restrict the movement of electromagnetic waves), extremely small thickness (increase the number of multiple reflections and dissipation of electromagnetic energy), the specific surface area large (improved interfacial polarization for reflection and dispersion of electromagnetic waves), and low mass density (reduce the vibration of the material by electromagnetic waves) offered by two-dimensional materials. In addition, two-dimensional materials should continue to exploit the layer-by-layer assemblies, core-shell structures and porous foams to increase the multimode attenuations of electromagnetic waves so that an electrical impedance matching occurs, which ensures electro-magnetic shielding to a wider range of electrical frequencies.

Graphene has the lowest shielding effectiveness between two-dimensional materials, but it can be exploited more efficiently in composite materials or hybrid materials. Scientific research on lightweight composite foams using polymers and graphene should promote future developments to further increase

the efficiency of electromagnetic shielding. Technological development and scientific research involved in the synthesis of composite or hybrid materials exploiting graphene as a material to increase shielding effectiveness should be developed for at least a decade. Despite the advances achieved so far, significant challenges must be overcome to achieve electrical conductivity and effectiveness to specific shielding effectiveness with desirable thicknesses using composite and hybrid materials based on two-dimensional materials. Scientific research and technological development related to the use of MXenes in synthesis of materials for electromagnetic shielding should be carried out by at least two decades. Unprecedented efforts must be made to theoretically predict the behavior of two-dimensional materials with respect to the shielding effectiveness against electromagnetic interference since each material has very different properties and structures.

CONCLUSION

In this chapter, the advantages of using two-dimensional materials such as graphene, transition metal dichalcogenides, MXenes and phosphorene as absorbent materials to electromagnetic waves as well as materials to increase the shielding effectiveness to electromagnetic interference in various areas of application were presented. The possibility of using hybrid and composite materials to improve the electrical and magnetic properties and thereby favor their application in electromagnetic interference shielding is illustrated through different examples with a wide variety of feasible combinations of materials. These materials can be applied in fields such as electromagnetic pollution, radar wave absorption, satellite communication, wireless telecommunications, in the care of human health, protection of electronic devices, aeronautical systems, space systems, and military systems.

KEY TERMS AND DEFINITIONS

Black Phosphorus (BP): Stable orthorhombic form of phosphorus with two-dimensional structure at room temperature and pressure of entangled rings with six members where each atom is linked to three other atoms.

Electromagnetic Interference (EMI) Shielding: Conductive or magnetic barrier material used to reduce the effect of the electromagnetic field in a space by blocking its effect.

Graphene: Allotrope of carbon formed by a single layer of carbon atoms located in a hexagonal lattice.

Mxene: Two-dimensional inorganic compound with thickness layers of few atoms based on transition metal carbides, nitrides, or carbonitrides.

Shielding Effectiveness: The product of 20 times the logarithm of the ratio between the incident emission and the transferred emission given in decibels (dB). A shielding effectiveness of 40 dB provides 99 percent attenuation of electromagnetic radiation that represents the minimum required for most applications.

Transition Metal Dichalcogenide: Chemical compound consisting of two chalcogenic anions (sulfur, selenium, tellurium) and at least one transition metal (molybdenum, tungsten, cobalt, etc.) with two-dimensional structure.

Two-Dimensional Material: Crystalline material consisting of a single layer of atoms or a single layer of two or more covalently bonding elements.

Effect of Nanoparticle and Inclination Angle at Thermal Efficiency in Heatpipes

INTRODUCTION

Recently, the proficiency of the engineering applications have become more notable. Continuous advancement have become essential in order to maintain the technology itself. Technology has improved significantly by accepting novel opinions and approaches for effective application, storage as well as transmission of energy. Nanotechnology is one of the most noteworthy fields which fascinates the researchers because of its superior capability, enabling a considerable advancement in the efficiency of several devices. Over the past few decades remarkable investigations have been carried out in order to implement nanotechnology in heat transfer usages. Nanofluids can be considered as a novel improvement in thermo-fluidics, acquired by stirring nano particles in conventional fluids (Choi, 1998). Investigators are taken nanoparticles of various metals, metal oxides, carbides, nitrides, as well as various kinds of carbon with several base fluids to be mentioned as water, ethylene glycol (EG) as well as engine oils.

Industrial engineering is one of the fields that artificial neural network, fuzzy logic, and nano technology have found an extensive implementation area (Razvarz et al., 2017; Jafari & Yu, 2018 ; Jafari & Razvarz, 2017, 2018, Jafari et al., 2016, 2018a, 2018b, 2019a, 2019b; Jafarian et al., 2012). Nanoscale refers size dimensions between approximately 1 and 100 nm (or more appropriately, 0.2 and 100 nm) because at this scale the properties of materials differ with respect to their physical properties from a larger scale.

The size dimensions of Nanoscale are among nearly 1 and 100 nm (or more suitably, 0.2 and 100 nm), since at this scale the attributes of materials change concerning their physical attributes from a greater scale. Every material which contains one or more dimensions in the nanoscale is stated as nanomaterial (Sekhon, 2014). Nanoparticles contain distinct biological attributes such as tiny size, a great surface-area-to-volume.

DOI: 10.4018/978-1-7998-3479-3.ch087

Nanofluids have been constructed by utilizing two techniques: one step technique and two step technique (Eastaman et al., 2001). The principal aim of these techniques is to provide a homogeneous as well as stable solid-liquid mixture, also avoiding the agglomeration, feasible erosion and clogging etc. In one step technique, the nanoparticles have been constructed and dispersed into the foundation fluid at the same time. Whereas in a two step technique, the nanoparticle has been generated in the first step and dispersed into host fluids in the second step. Investigation reveals that nanofluids with oxide nanoparticles and carbon nanotubes can be produced utilizing two step technique. Two step technique is not appropriate for metallic nanoparticles. Under particular circumstances, nanofluids represent excellent thermo physical features that result in better effect of the thermal usage (Singh & Raykar, 2008).

Currently, so many investigators have suggested mechanisms of increment in heat transfer via nanofluid as the affect of Interface, Brownian motion, Ballistic conveyor of energy carriers as well as thermophoresis. The first attempt in adding nano materials or particles in the liquid was reported by Choi in (Choi et al., 1999; Choi, 1995; Pinto & Fiorelli, 2019) which was named nanofluid in 1995. It is a novel class of heat transfer as well as cooling working fluid. In (Kebllinski et al., 2005) the authors analyzed the consequence of adding nanoparticles to liquid which improved defects of past that the adding of millimeter as well as micro meter scale particles may lead to the sedimentation and pipe block. The heat transfer specifications of nanofluid are discussed in (Lin et al., 2008). The mechanisms that are responsible for the increment in thermal conductivity of nanofluids are investigated in (Chandrasekar et al., 2010; Ren, 2019). Furthermore, several mathematical models for identifying various factors as well as their limitations have been investigated in recent years. In (Murshed et al., 2005; Wang et al., 2017) the authors have been proposed that the nanoparticles shape, size as well as volume fraction are the principal parameters for deciding the thermal conduction of nanofluids. The applications as well as the challenges of nanofluids have been studied in (Saidur et al., 2011).

Heat pipe is considered as a device utilized in conduction the heat from one place to another. They are passive systems which convey heat from a heat origin (evaporator) to a heat sink (condenser) over lengthy intervals through the hidden heat of vaporization of a working fluid. The heat pipe can be theoretically classified into three parts, the evaporator, the adiabatic section, as well as the condenser. A bare heat pipe structure is demonstrated in Figure 1. In procedure, the working fluid attracts the heat from the heat source, then evaporates in the evaporator. The warm vapor straightly runs via the adiabatic part, and then condenses in the condenser. The condensed working fluid in the condenser runs back through capillary construction on the internal wall in the adiabatic part and then attains the evaporator once more. The idea of the heat pipe was initially represented in (Gaugler, 1944; Trefethen, 1962; Rakesh & Bumatraria, 2019), however, was not extensively published up to an independent growth by (Grover et al., 1964) at the Los Alamos Scientific Laboratories. Thermosyphon heat pipe is an empty, closed, and evacuated pipe which contains a working fluid. It is partitioned into three parts: evaporator, adiabatic, and the condenser part. The working fluid attracts the heat in evaporator part, and then gets transformed into the vapor phase that moves to the condenser part because of the pressure variance, declines heat to the cooling media via the condenser part and consequently gets transformed into the liquid phase.

BACKGROUND

The main constituents of a heat pipe are a sealed container, a wick construction, as well as a working fluid. All these components are working simultaneously in order to convey the heat more effectively and evenly. The wick construction is positioned on the internal area of the heat pipe wall, also is saturated

with the liquid working and makes the construction to produce the capillary action for liquid regression from the condenser to the evaporator. Regression of the liquid to the evaporator from the condenser is produced by wick construction.

Heat Pipe Container Sealed Containment Shell or Vessel

The container, working fluid, as well as wick construction of a heat pipe specify its operational specifications. One of the most significant factor in selecting the material for the heat pipe container as well as the wick is its adaptability with the working fluid. Decay of the container or wick as well as the pollution of the working fluid because of the chemical reaction may critically weaken heat pipe efficiency. For instance, the noncondensable gas generated during a chemical reaction ultimately may stack near the end of the condenser, reducing the condensation surface region (Naveen Kumar Gupta, 2019). This decreases the capability of the heat pipe to transfer heat to the exterior heat sink. Furthermore, the material as well as the geometry of the heat pipe container should have a supreme burst power, low weight, supreme thermal conductivity, as well as low porosity.

Because of the gravity, the condensed working fluid comes back into the evaporator part. So, the heat is attracted continuously via the evaporator part also is freed by the condenser part. There exist several kinds of heat pipes, which are extensively utilized in various usages to be mentioned as micro grooved, mesh wick, sintered wick, oscillating, and thermosyphon etc.

Working Fluid

The wick generates the construction for developing the capillary action for the liquid comes back from the condenser (heat output/sink) to the evaporator (heat input/source). As the heat pipe has a vacuum, the working fluid boils and takes up the hidden heat at well below its boiling point at atmospheric pressure. For example, the water boils at only over 273°K (0°C) and starts to efficiently convey hidden heat at this down temperature. The selection of the heat pipe working fluid is based on the operating temperature range of the usage. Working fluids range from liquid helium for exceedingly down temperature usages (-271°C) to silver ($>2,000^{\circ}\text{C}$) for exceedingly supreme temperatures. Water can be considered as one of the most usual heat pipe working fluid for an operating temperature range from 1°C to 325°C . Down temperature heat pipes utilize fluids like ammonia as well as nitrogen. High temperature heat pipes use cesium, potassium, NaK as well as sodium ($873\text{--}1,473^{\circ}\text{K}$). the range of working of some fluids are presented in Table 1.

In experimental/theoretical researches, investigators have utilized various kinds of nanofluids to be mentioned as Aluminium oxide (Do et al., 2010a; 2010b; Putra et al., 2012, 2014; Noie et al., 2009; Kamyar et al., 2013; Heris, 2014; Ji et al., 2013; Qu et al., 2010, Hung et al., 2012; Mashaei et al., 2016) Copper oxide (Wang et al., 2010, 2017, Liu et al., 2010, 2007, 2013; Liu & Zhu 2011; Venkatachalapathy et al., 2015; Putra et al., 2014; Chen et al., 2013; Alizad et al., 2012), Copper (Liu et al., 2011; Kole & Dey, 2013; Sokomon et al., 2012; Senthikumar et al., 2012; Riehl & Santos, 2012; Wan et al., 2015; Chen et al., 2013; Solomon et al., 2012, 2014) Magnesium oxide (Menlik, 2014), ferric oxide (Liu et al., 2013 Goshayeshi et al., 2015, 2016; Huminic & Huminic, 2013), Silicon dioxide (SiO_2) (Gunnasegaran et al., 2015, 2013; Qu & Wu, 2011; Chen et al., 2013), Titanium dioxide (Shafahi et al., 2010; Alizad et al., 2012) and Zinc oxide (Saleh et al., 2013) etc. in order to acquire the increased thermal performance. Thermal performance contains thermal effectiveness, thermal resistance, the efficient thermal conduc-

Potassium	673-1298

tivity of heat pipe, surface temperature gradient, convective heat transfer coefficient at evaporator and condenser part etc.

Wick Structure

The heat pipe wick construction utilizes capillaries for removing the liquid working fluid from condenser back to the evaporator part. The heat pipe wick construction is made of different materials and approaches. The most popular heat pipe wick construction has axially grooves on the internal heat pipe vessel wall. The wick construction as well as the working fluid produce the capillary forces needed to pump liquid from the condenser to the evaporator, also hold liquid equally spread in the wicking material. The heat pipe wicks are categorized into homogeneous wicks and composite wicks. Homogeneous wick is made of a single material as well as configuration. The most well-known kind of homogeneous wicks are wrapped screen, sintered metal as well as axial groove. Composite wick is made of two or more materials and configurations. The most popular kinds of composite wicks are variable screen mesh, screen-covered groove, screen slab accompanied by grooves, as well as screen tunnel accompanied by grooves. However, the required material features as well as the constructional properties of heat pipe wick constructions are a supreme thermal conductivity, supreme wick porosity, tiny capillary radius, and supreme wick permeability (Ghanbarpour et al., 2015a, 2015b; Senthil et al., 2016).

Figure 1. wicks contain single materials (left) wicks contain two or more materials(Right)

The wick helps the liquid to flow from the condenser to the evaporator part of the heat pipe. Furthermore, it supplies surface pores, which are essential at the liquid–vapor interface in order to develop the needed capillary pressure. Besides, the wick construction effects the radial temperature fall at the evaporator end among the internal heat pipe surface as well as the liquid–vapor surface. Hence, an efficient wick needs great inner pores in a direction normal to the heat flow way. This will cause a minimization in the liquid flow resistance. Moreover, tiny surface pores are needed in order to develop a supreme capillary pressure as well as a great conductive heat flow direction in order to minimize the radial surface to liquid–vapor surface temperature fall. For satisfying these necessities, two kinds of wick construction are generated. These are the homogeneous wicks which are constructed of a single material, and the composite wicks contain two or more materials, see Figure 1.

EXPERIMENTAL SETUP AND APPROACH

Characterization and Preparation of Aluminium Oxide Nanofluids

The fluid used in this experiment is pure water, also Aluminum oxide nanoparticles are the most popular nanoparticles utilized with 30 nm as well as 45 nm in size evaluated by transmission electron microscopy (TEM). The TEM photograph and XRD pattern of Aluminum oxide nanoparticles along with particle size around 35 nm added to pure water is demonstrated in Figure. 2. The nanofluid utilized in this experiment is constructed of 99.0% pure Aluminum oxide along with an average particle size of 35nm pre-dispersed in water also the precursors for its thermal deposition are trimethylaluminum (TMA) and water. Moreover, XRD is utilized in order to trace the transformation of Aluminum oxide. It is clear from this Figure that Aluminum oxide is observed in the as-sprayed nano particles. Aluminum oxide particles true density is considered to be 3880 kg/m^3 that is able to convert into weight fraction as well as volume fraction. The nanoparticles as well as the pure water are combined by using an ultrasonic homogenizer with the precision of 0, 1% as well as 3% by weight. Aluminum oxide nanoparticles are produced by means of a catalytic chemical vapor deposition approach. Aluminum oxide nanomaterials are synthesized by utilizing precursors to be mentioned as methane, acetylene, toluene, xylene, benzene, etc. However, it is possible to apply any kind of hydrocarbon or carbonaceous materials for the synthesis of Aluminium oxide nanomaterials.

Figure 2. TEM photograph(Left)and XRD Pattern (Right) of Alminium oxide nano-particles.

Experimental Setup

The schematic diagram of the heat pipe under consideration is demonstrated in Figure 3. The loop is made of a test part, cool water loop as well as data recording system. The water flow at a fixed amount is considered to be 1.7 L/min. The inlet temperature of the water is controlled and also is set at the temperature of $20 \pm 0.5^\circ\text{C}$ by utilizing a thermostatic bath for achieving a steady working temperature during the time that the heat input increases. The close-loop of the evaporator is designed in such a manner that it has the cold water inside the storage tank with 0.125 m^3 volume and water pump. Experiments are done at different heat fluxes as well as three various tilt angles. Position of the heat pipe tilt angle is displayed in Figure 3. Also the temperature of the laboratory is adjust to $25 \pm 1^\circ\text{C}$. The heat pipe which is used in the experiment is a straight copper tube having outer diameter 8 mm as well as length of 190 mm, also has 1 mm wick-thickness copper powder (140-200 nm) sintered wicked. The implemented heat pipe is made of three parts to be mentioned as an evaporator, an adiabatic part as well as a condenser. The condenser part of the plain heat pipe is placed vertically into the cooling chamber for removing the heat from the condenser part with the help of forced convection to a steady temperature bath. In order to heat the evaporator part, a 0-220 V AC electric heater is utilized. Electric power acquires with the measurement of the current imparted to the electric heater as well as the voltage across the heating resistor. In order to reduce the contact thermal resistance among the heater as well as the heat pipe, the electrical heater is glued with thermal grease master cooler-HTX3-GL.

Test Scheme

Once the power supply is turned on, the power is raised. Nearly 15-25 min are needed for the tests in order to attain steady state. The moment that the steady-state condition is attained, the temperature distribution in the heat pipe along with the other experimental parameters is measured and recorded. Henceforth,

The local heat pipe temperature can be evaluated by utilizing four isolated type-T thermocouples. A digital temperature recorder is implemented in such a way that all thermocouples are linked to it. Thermocouples (having the uncertainty less than 0.1 °K) are spread along the surfaces of the heat pipe section in such a way that one thermocouple is connected to the center at evaporator part, two thermocouples are connected to adiabatic part, also one thermocouple is connected to condenser part. Furthermore, a heater Bar (maximum 90W) is utilized as a heat source in the heating part. Therefore, the heating load (Q) as well as the temperature differences (ΔT) are calculated. The thermal resistance associated with the thermosyphon heat pipe is defined as follows,

$$R = \frac{\Delta T}{O} \left[\frac{\circ K}{W} \right]. \quad (1)$$

$$\eta = m_w C_p (T_{wout} - T_{win}) / (V.I). \quad (2)$$

where m_w is taken to be the mass of water, C_p is taken to be the specific heat capacity of water, T_{wout} and T_{win} are the temperature of water in output and input of condenser respectively, also V and I are considered as the voltage and the current of heat source in evaporator part, respectively.

In order to cause the heat pipe to function in the highest capillary pumping pressure, $\Delta P_{c,max}$ should be more than the total pressure fall in the pipe. The pressure fall is constructed of three components which are mentioned as follows,

1. The pressure fall ΔP_l needed to return the liquid from the condenser to the evaporator.
2. The pressure fall ΔP_v needed to make the vapour to flow from the evaporator to the condenser.
3. The pressure because of the gravitational head, ΔP_g , that can be zero, positive or negative, related to the inclination of the heat pipe.

The following relation is extracted (Tien & Rohani, 1974),

$$\Delta p_{c,max} \geq \Delta p_l + \Delta p_v + \Delta p_g. \quad (3)$$

In a case that Equation (3) is not hold, the wick will dry out in the evaporator area also the heat pipe will not function. The highest permitted amount of the heat flux for holding the equation (3) is considered as the capillary limit. Generally, the capillary limit determines the highest amount of heat flux over much of the function domain, nevertheless, the deviser should investigate that a heat pipe is not needed to operate outside the envelope either at design conditions or at start-up.

RESULTS AND DISCUSSIONS

The shape of the heat pipe as well as the working fluid has an important consequence on its efficiency. Hence, the proposed experiment in this book chapter considers different conditions of fluid for evaluating the temperature distribution of heat pipe where the condenser as well as evaporator is perpendicular line pipe. Figure 4 demonstrates the wall temperature distribution based on the length of the heat pipe axial and under the water cooling in a case that Al_2O_3 nanoparticles adds into the working fluid. The increment in the heat pipe wall temperature variance is less than the pure water filled heat pipe under different heat loads.

Figure 5. displays the consequence of nanoparticle on the temperature variance of the heat pipe under different input powers. It can be seen from this Figure that by increment in the heat flux, a sudden decrease happens which can cause an improvement in the valve of vapor as well as the rate of transnational speed among condenser and evaporator. Figure 6. displays evaluated value of thermal resistance of the heat pipe with nanofluid as well as the decrement of the thermal resistance by increment in the input power while the nanofluid is added.

The cause of the increment in the heat pipe thermal can be given as below:

Implementing of the existing heat pipe as well as nanofluid theories, especially the ones associated with the boiling limit, can cause a decrement in the boiling limit. The reason of this decrement is the effect of the increment of the liquid conductance in heat pipe. Hence, the thermal resistance of the heat pipe has decrement for the same cause. The high efficiency of the nanofluids demonstrates nanofluid potential as substitutions conventional pure water in grooved heat pipe.

The increment of the convective heat transfer coefficient is associated with the increment of the fluid thermal conductivity. Also, the increment of the thermal conductivity of the nanofluids depends on the increment of the volume concentrations. Adding nanoparticles to liquid considerably makes better the energy transport procedure of the base liquid. A smaller particle size would provide a much larger surface

Figure 4. Average temperature of heat pipe distribution in different heat load.

area for molecular collisions and therefore increase the rate of reaction, making it a better catalyst and reactant. A tiny particle size can generate a great surface region for molecular collisions, also can make an increment in the amount of reaction, causing it a superior catalyst as well as reactant.

The shape of heat pipe, working fluid as well as the consequence of gravity has a significant effect on its performance. This experiment implements various conditions for fluid to evaluate the temperature distribution of heat pipe as well as cooling water evaporator and condenser. In vertical form the vapor bubbles that get heat in the evaporator increase in size. Their own buoyancy make them to grow in the tube part. The growing bubbles in the tube makes the liquid slugs to move downwards unto the evaporator with the help of the gravity force. In the horizontal form (90° inclination angle) of function, there exists no macro motion of bubbles. This can make a conclusion that the gravity has a role in the heat pipe. As

Figure 5. Effect of nanoparticle on the temperature difference of heat pipe under different input power.

Figure 6. Measured value of thermal resistance of heat pipe with nanofluid

the gravity force has no effect, all the movements related to the bubbles as well as slugs should be carry on with the help of pressure forces. These forces are generated because of the temperature variation which are among evaporator as well as condenser.

Figure 7 demonstrate the alteration of thermal performance associated with the heat pipe. In order to generate various results, fluids with different concentration percent of Al₂O₃ nanoparticles at 30, 60 as well as 90 tilt angles are utilized. The increasing of the tilt angle can make the increment of flow back into the evaporator part. With increasing of the title angle from 0 to 60 the thermal performance grows. However, in a case that the increasing be more than 60 the thermal performance will reduce. This is due to the impact of incrementing gravitational force among evaporator part as well as condenser

Figure 7. Alteration of thermal performance of heat pipes by different tilt angles and fluids of heat pipes at 30W, 40W and 50W power.

part. In a case that the tilt angle of heat pipe is constant, the performance of the thermal conductivity increases by adding nanoparticles to the base fluid. Adding extra nanoparticles to fluid can transform the property of working fluid at evaporator part into the solid phase. Furthermore, it causes a decrement in the convection efficiency of nanofluid inside evaporator part. Figure 8 demonstrate that at the constant angle of the heat pipe, the increasing of the heat rate will increase the performance of the heat pipe. It is clear from these Figures that after the tilt angle of 60° (Figure 8) the heat pipe performance is reduced. From these Figures it can be seen that the contact angle makes the condensed vapor to return rapidly into the evaporator part with gravity also, less thermal resistances as well as better heat transfer coefficients are extracted.

Figure 8. Variations of Thermal efficiency in different heat rate at 60° and 90° tilt.

FUTURE RESEARCH DIRECTIONS

The investigation of the thermal enhancement of the heat pipe proposed by different nanofluid will be the further work.

CONCLUSION

In this book chapter, an experimental research of the thermal enhancement related to the heat pipe is carried out proficiently by adding Al_2O_3 nano powder to pure water in side 1mm wick-thickness sintered circular heat pipe in various title angle.

Important conclusions have been obtained and are summarized as following:

- The ideal value of thermal efficiency obtains at the concentration of 1.0% wt nanofluid.
- The heat transfer coefficient increases with increasing the applied heat flux at the evaporator.
- Adding Al_2O_3 nanoparticles to pure water could enhance the thermal efficiency of heat pipe.
- With enhancement of the heat flux, the heat pipe efficiency tends to increase.
- The lowest amount of temperature in the heat pipe can be observed in the curved zone and this amount of temperature is decreased from the evaporator to the curve and then increase.
- Effects of heat pipe tilt angle on the thermal efficiency are checked and is shown that it can be increased at higher tilt angle.
- The inclination angle has a great effect on the heat pipe thermal resistance using water as the working fluid.
- The heat pipe thermal efficiency get enhanced with increasing nanoparticles concentrations and tilt angles.

KEY TERMS AND DEFINITIONS

Aluminum Oxide: A chemical compound of aluminum and oxygen with the chemical formula Al_2O_3 .

Condenser: A device that cools gases into liquids.

Evaporator: A vessel or stage which turns a liquid into vapor.

Heat Pipe: Tubular device that is very efficient in transferring heat.

Heat Transfer: The movement of thermal energy from one thing to another thing of different temperature.

Nano Materials: Materials of which a single unit is sized between 1 to 1000 nanometers (10^{-9} meter)

Nanofluids: A fluid containing nanometer-sized particles, called nanoparticles.

Thermal Resistance: The ability of a material to resist flow of heat.

Thermosyphon: A device that transfers heat via natural convection in a fluid.

Modeling of the Aerodisperse Systems Hydrodynamics in Devices With Directional Motion of the Fluidized Bed

INTRODUCTION

Among various dispersed flows, fluidized bed plays the most significant role in modern technology. The fluidization technique has become widely used due to high intensity of processes.

Disadvantages of the fluidized bed device can include (Philippsen et al., 2015), (Haron et al., 2017), (Huili et al., 2017): different residence time of a particle in the device, a need for thorough cleaning of the exhaust air and material entrainment (in particular it is applicable to small particles of the system). In addition, a significant drawback is the return of fine particles back in the fluidized bed zone. The analysis of various fluidized bed granulation equipment in chemical (Caiyuan et al., 2004), food (Patel et al., 2011) and pharmaceuticals (Agrawal and Naveen, 2011) industries showed the urgent need to organize the mutual flow motion, which will enhance the quality of the final product.

It is rational to use the same device for multiple processes in low-tonnage and multi-assortment production in order to reduce the range of the equipment. Implementation of the new forms to organize mutual flows motion (while keeping the same principles of the fluidized phases contact), which would intensify processing of the dispersed materials without considerable increase in the energy costs, is a promising direction for the development of heat and mass exchange processes in the heterogeneous systems (Artyukhov et al., 2019), (Van Ommen et al., 2012).

Among the major techniques of controlling the polydisperse particles residence time in the device, one should notice the following:

1. To develop a direct movement of particles using accelerating elements (gas distributors of vortex type) (Sklabinskyi and Artyukhov, 2013).
2. To design the device with a variable cross-sectional area applied to the granulation, cooling and dedusting process (Ostroha et al., 2019).

DOI: 10.4018/978-1-7998-3479-3.ch088

3. The promising direction to reduce financial and energy costs on the heat and mass transfer processes in the fluidized bed is the application of sectioning (vertical and horizontal) to create different conditions for the particle heightwise (lengthwise) motion in the device (Yukhymenko et al., 2016).

BACKGROUND

There are various possibilities to apply suspended layer (fluidized bed, weighted layer). There are many successful cases regarding the introduction of this method in industrial practice, while in others it is at the stage of laboratory research. The processes taking place in heterogeneous systems using the suspended layer method have a great industrial application. It can be used to stove sulphide, arsenic and antimony ores to facilitate the extraction of gold or silver, for pyrite and pyrrhotine roasting to obtain SO_2 in the production of sulfuric acid.

The suspended layer is in great demand in metallurgy for stoving of copper, cobalt and zinc sulfide ores to obtain valuable metals.

Fluidized bed devices for drying solid materials (coal, cement, limestone, etc.) are known in the whole world. Economic considerations make the use of these devices particularly interesting when large-tonnage materials are to be processed. A suspended layer dryer can also be used as a classifier since the drying and classification processes take places simultaneously in the device.

The way to obtain granulation products in the fluidized bed (suspended layer) is used by the world well-known manufacturers of fertilizers and pharmaceutical products: Urea Casale S. A. (Switzerland), Kahl Group (Germany), Stamicarbon (Netherlands), Toyo Engineering Corporation (Japan), Changzhou Xianfeng Drying Equipment Company Ltd (China) Glatt (Germany), Uhde Fertilizer Technology (Netherlands), Rottendorf Pharma (Germany) (Saikh et al, 2013).

The world practice of recent years in the small power engineering has shown that the fluidized bed technology is effective for the utilization of different biomass types, industrial waste and effluents.

The development and implementation of fluidized bed devices are held back in many industries by the lack of reliable methods for calculating them. One of the main reasons is the lack of knowledge of complex and varied processes in the fluidized bed.

When constructing a mathematical model, one should take into account that there is a huge amount of particles in the operating device (Palappan and Sai, 2008). These particles are of different sizes and they move at a different rate in all directions (Ostroha et al., 2017).

Mathematical modeling lets to establish and to optimize mode and technological parameters of the investigated process, as well as to minimize the use of additional automation tools (Trojan, 2015), (Zimmermann and Taghipour, 2015), (Zhaofeng, 2006).

The flows motion hydrodynamics modeling is carried out by the finite-volume method (a numerical method of the differential equations system integration in the differential derivatives). An important benefit of the finite-volume method is that the conservation law of integral values (of the flow rate, of motion quantity) is implemented on every chamber of the computational grid, but not only within it, due to the strong thickening of the computational grid. A closed area of the fluid or gas flow is selected in the calculation. The macroscopic values fields (in this paper – velocity), describing the environment in time and satisfying the definite laws, formed mathematically, are searched for it. The conservation laws in Eulerian variables are mostly used. This model is the most common and the most complicated among multi-phase flow models. The substance of every phase is a solid phase, and the substance motion of

every phase is modeled with Navier-Stokes (Reynolds) equations system, equation of continuity and energy. According to this model, the motion equations for every phase, are solved together.

In order to carry out modeling, it is convenient to solve the above equations by the numerical methods (DEM - Discrete Element Method), identifying a discrete set of values in the proper place (mesh, node of grid), space (during the stationary regimes of the flows motion) instead of the continuous solution. In order to achieve the maximum accuracy of solutions, that method to demonstrate discrete values is chosen, which due to the discretization complies with algebraic equations analogues. As a result, the mathematical problem to solve the differential or integral equations system can be reduced to the algebraic equations system.

There is also a method to describe the axisymmetric motion of the swirling gas flow, based on a system of Navier-Stokes equations (1) and the continuity equation (2) (Artyukhov and Sklabinskyi, 2015):

$$\frac{\partial}{\partial t}(\rho_g V_i) + \frac{\partial}{\partial q_j}(\rho_g V_i V_j) = -\frac{\partial p}{\partial q_i} + \frac{\partial}{\partial q_j} \left[\varepsilon \left(\frac{\partial V_i}{\partial q_j} + \frac{\partial V_j}{\partial q_i} \right) \right] + f_i, \quad (1)$$

$$\frac{\partial \rho_g}{\partial t} + \frac{\partial}{\partial q_j}(\rho V_j) = 0, \quad (2)$$

where ε is a coefficient of turbulent viscosity; t – time; V_i – instantaneous component of the velocity on the given axis; ρ_g – gas density; p – pressure; f_i – component, characterizing the action of the bulk forces; q_j – axes of coordinates.

Analysis of the previous works in the two-phase flows modeling sector, which consists of gas as a disperse phase and disperse particles, showed that one of the most perspective methods to calculate the motion of the particles is a trajectory method (Khanali et al., 2013). Authors (Goldschmidt et al., 2003) concluded that in case of the compressed motion modeling of particles with large diameter (0.5-5 mm), the Lagrangian model regarding the force analysis of the particle motion by the differential equations of motion forms the base for it. The trajectory method with highly accurate results can be used only if there is any software which enables to export theoretical model of the single-particle motion and to consider the flow constraint degree.

The motion of particles in the workspace was simulated on the basis of the differential equations system of the particle motion (Artyukhov et al., 2017):

$$\left. \begin{aligned} m \frac{d^2 q_1}{dt^2} &= -g + \psi \cdot \frac{\pi \cdot \mu_g \cdot d}{8 \cdot m} (V_1 - W_1), \\ m \frac{d^2 q_2}{dt^2} &= \frac{W_3^2}{r} + \psi \cdot \frac{\pi \cdot \mu_g \cdot d}{8 \cdot m} (V_2 - W_2), \\ m \frac{d^2 q_3}{dt^2} &= -\frac{W_2 W_3}{r} + \psi \cdot \frac{\pi \cdot \mu_g \cdot d}{8 \cdot m} (V_3 - W_3) \end{aligned} \right\}, \quad (3)$$

where m – particle's mass; r – a current radius of the workspace in a unit; W_1, W_2, W_3 – radial, circumferential and flow rate components of the particle's velocity correspondingly; g – gravitational acceleration; ψ – a linear coefficient of particle resistance to the gas flow; μ_g – gas flow viscosity; d – a particle's diameter.

Criteria to choose the two-phase system flow model are the following.

1. *Ratio β of the disperse phase substance mass (d) to the mass of the carrier phase substance (c):*

$$\beta = \gamma \frac{F_d}{F_c}, \quad (4)$$

where F_d and F_c – volume fractions, γ – the ratio of the disperse phase density to the carrier phase density, $\gamma = \rho_d / \rho_c$.

If β has high values, the dispersed particles have a great impact on the carrier phase flow, so it is necessary to use only the multi-phase Eulerian model for the proper flow modeling.

2. *Stokes number St :*

$$\beta = \gamma \frac{F_d}{F_c}, \quad (5)$$

where t_d – time, which describes the particles motion, $t_d = (\rho_d d_d^2) / (18 \mu_c)$, d_d – diameter of the particle, μ_c – viscosity of the carrier phase substance, $t_c = L_c / U_c$ – time, which describes the carrier phase, L_c – characteristic length, U_c – characteristic velocity.

The authors (Gidaspow, 1994), (Crowe, 2006), (Sinaiski, 2010), (Marchisio et al., 2013) suggest taking into account the constrained mode of motion when we calculate the particle residence time in the workspace of the device

$$\tau_{AB} = \tau f_{\tau}(\psi), \quad (6)$$

where τ_{cm} – velocity of the constrained motion of particles in the disperse phase; τ – a velocity of a single particle motion; $f_{\tau}(\psi)$ – an empirical influence function of the constraint conditions on the residence time of a particle in the workspace.

The function $f_{\tau}(\psi)$ is:

$$f_{\tau}(\psi) = (1 - \psi)^{-m}, \quad (7)$$

where m – an empirical measure of the stage (a constraint coefficient for the time calculations).

Ansys CFX and Ansys Fluent (<https://www.ansys.com>) software is based on a finite-volume method of solving hydrodynamic equations and using a rectangular adaptive mesh with local grinding. In order to approximate curvilinear geometry with higher accuracy, the technology of geometry grid density is used. This technology enables to import geometry from CAD systems and to share information with finite

element analysis systems. This technology has solved the problem of automatic mesh generation – in order to generate a mesh, it is enough to set only a few parameters, after which the mesh is automatically generated for a computational area that has the geometry of any complexity degree.

The calculation starts with some initial approximation set as the initial data. At each global iteration, the velocity and pressure fields, obtained after the time specified as the integration step, are calculated. The stationary solution of the problem is achieved after a sufficiently large number of global iterations corresponding to a long period of time.

When performing the calculation, the program automatically breaks the calculation area into separate subareas, subdomains, the size of which is proportional to the velocity of the appropriate processor. The calculation algorithm works in such a way that each processor calculates the flow only in its own subdomain, and after each global iteration, the resulting solution is “adhesion”. The parallelization algorithms used in modern software products let to achieve acceleration with an efficiency close to 100%. In other words, the calculation time is inversely proportional to the total computing power

As a rule, the adhesion condition is set as boundary conditions on all solid walls (the velocity is zero), the distribution of all velocity components in the inlet section, and the first derivatives (in the direction of flow) of the velocity components in the outlet section are equal to zero. In practice, if the flow rate at the inlet is approximately uniform in the intersection, the user sets only the average velocity (or flow rate) at the inlet, and sets nothing at the output - it is assumed that the user chose the output section far enough from the areas of intensive restructuring of the flow.

Examples of successful application of computer modeling for various processes of chemical technology are presented, in particular, in (Zhaofeng, 2006), (Liu et al., 2012), (Wang al., 2015), (Li and Li, 2016), Tahvildari et al., 2016).

MAIN FOCUS OF THE CHAPTER, RESULTS AND DISCUSSION

The qualitative picture of the typical regimes regarding the equipment operation is demonstrated below.

Vortex Granulator

Regime I. Gas flow filtering through the stationary layer of granules (fig. 1a). The layer is motionless, gas flow passes through pores in the layer.

Regime II. Beginning of the granules layer motion (fig. 1b). In this regime, the lower parts of the layer are partially weighted, while the upper parts of the layer are still motionless.

Regime III. Partially fluidized bed (fig. 1c). Granules in the lower parts of the layer are in the weighted state and move along the circular trajectory with low intensity, the granules in the upper parts of the layer are motionless. At a certain gas velocity, the whole layer goes into the weighted state.

Regime IV. Fluidized bed with partial swirling (fig. 1d). Granules in the weighted layer take the wave trajectory, which is characterized by the localized vortex motion, started in any random place of the layer. The vortex is spread in that part of the layer, which is above the gap of the gas-distributing device, and the rest of the area is in the suspended state. With an increase of the gas velocity, the growing number of granules is drawn into the vortex motion.

Regime V. Developed vortex fluidized bed (fig. 1e). With further increase of the gas velocity, the process of waves formation is weakened, the weighted layer has the ordered vortex structure.

Figure 1a. Typical regimes of the vortex granulator operation: gas flow filtering through stationary layer of granules

Figure 1b. Typical regimes of the vortex granulator operation: beginning of the granules layer motion

Figure 1c. Typical regimes of the vortex granulator operation: partially fluidized bed

Figure 1d. Typical regimes of the vortex granulator operation: fluidized bed with partial swirling

Figure 1e. Typical regimes of the vortex granulator operation: developed vortex fluidized bed

Figure 1f. Typical regimes of the vortex granulator operation: stable ablation regime of granules

Regime VI. Stable ablation regime of granules (fig. 1f). Space over the vortex weighted layer of the material is filled with the solid phase, and the difference between the vortex weighted layer and overlayer space consists only in the concentration of the solid material. There is a gradual reduction of the granules concentration in the overlayer space with an increase of the height. Granules leave the vortex layer; their ablation is caused by the domination of the upward flow gas force over the gravity force.

Shelf Multistage Device With a Weighted Layer

In the upper section of the device the inclined shelves (angle of lean 30°) with ratio l/B (where l is the distance from the end of the shelf to the wall of the device; B – width of the device) in the amount of $l/B=1$ (free channel) to $l/B=0.3$ were installed. The results of the previous investigations (Yukhymenko et al., 2016), show that the efficiency to extract the small fraction (with the size less than 1 mm) into the ablation has the maximum value with the ratio $l/B=0.5$.

Thus, at the first stage of theoretical studies, it was necessary to find the optimal value of the free area in the shelf for the ablation efficiency of the fraction less than 1mm.

The results of the computer modeling show that the efficiency to extract the small fraction into the ablation is achieved with the reduction of the perforation degree of the shelf. While installing the solid shelf in the separation zone of the device (fig. 7), the whole gas flow guaranteedly passes through the outloading space. It defines the extraction of the small fraction of the material precisely in this zone. 5% of perforation in the shelf causes the redistribution of the gas flow, directing its share through the hole in the shelf. Therefore, the gas flow intensively is interconnected with the material and not only in the outloading space zone but also on the shelf surface. It causes the increase of the fraction ablation efficiency, which is less than 1 mm.

The further increase of the free area of the inclined contact shelf is followed by the reduction of the small fraction extraction efficiency into the ablation. It is explained by the increased effect of the gas flow redistribution. The gas flow velocity in the outloading space decreases so much that the small fraction extraction process of the material in this zone is not very intensive. The total area of holes does not provide sufficient phase contact (Yukhymenko et al., 2016).

There are three perforated shelves in the drying (granulation) zone of the device. Moreover, while changing the distance between the end of the shelf and the wall of the device, it is possible to create different velocities of the gas flow

Regime I. Transition regime (figs 2a,b). The upward gas flow force in this regime causes the gradual change of its motion trajectory from the translational to the pulse-forward ones in direction of the outloading gap. Therefore the dispersed material starts to move into the weighted state, and the inertial force is compensated by the upward flow force of the drying agent.

Regime II. The weighted layer regime (fig. 2c). The effect, made by the upward flow of the heat transfer agent in such regime leads to the creation of the stable weighted layer thanks to the compensation of the inertial force and the rolling-down force on the sloping surface. The gas flow velocity reaches the first critical value, then it increases and is within the range of the working velocity.

Regime III. The regime of the developed weighted layer (fig. 2d). This regime is described by a dominant effect of the upward gas flow force on the dispersed material and by the increase of its displace-

ment vertical component. Therefore, at first, the share of the dispersed material is taken out from the surface of the shelf and then it moves to the outloading gap.

Figure 2. Typical operation regimes of the shelf multistage device (dryer or granulator): a – separation of the small fraction in the shelf dryer (granulator); b – transition operation regime of the dryer (granulator); c – weighted layer regime of the dispersed material motion; d – developed weighted layer regime of the dispersed material motion

SOLUTIONS AND RECOMMENDATIONS

The above results for the modeling of the operating regimes in devices let to select the following optimal parameters to implement the target process:

- configuration of the workspace in the device and the way to create the directed motion of the dispersed phase flow;
- duration of the dispersed phase in the workspace of the device;
- technological features of the related processes (separation, classification, heat exchange)
- properties of the raw material and commodity product – temperature and humidity features, fractional composition, hardness index, special properties (porosity, selectivity etc.).
- energy indicators of the process implementation.

In general, the algorithm to calculate the device with the directed fluidized bed can be represented by means of blocks (fig 3), which are logically interconnected between each other. The peculiarity of the algorithm includes its universality and ability of “flexible” implementation of separate blocks.

Figure 3. Block-scheme of the granulation unit calculation

The modeling and calculation results with the use of authors' software, description of which is represented in the work (Artyukhov and Artyukhova, 2018), are exported to the cluster Granulation Unit[®] in the form of separate structural blocks (fig. 4).

Figure 4. Cluster Granulation Unit[®]

Fig. 5 demonstrates the technological scheme of the porous ammonium nitrate production. In this scheme the devices, operating regime modeling of which is shown above, are used as the main technological equipment.

Elements of the installation:

VG – a vortex granulator; H – a heater; GSD – a gravitational shelf dryer; FBC – a fluidized bed cooler; A – an absorber; F – a filter; M – a mixer; B – a batcher; HP – a hopper; G – a gas blower; P – a pump; T – a tank; C – a compressor.

Figure 5. A unit for the production of PAN granules by using a vortex granulator (multistage shelf granulator) and a gravitational shelf dryer (Artyukhov and Artyukhova, 2018)

The main flows:

1-1 – a seeding agent; 2-2 – manufacturing air; 3-3 – polluted air; 4-4 – purified air; 5-5 – polluted water; 6-6 – water; 7-7 – substandard granules; 8-8 – air for the spraying of the liquid materials (solution, melt); 9-9 – the product; 10-10 – air for cooling of granules; 11-11 – granules for packaging; 12-12 – steam; 13-13 – dusty gas; 14-14 – liquid materials (solution, melt); 15-15 – water condensate; 16-16 – a drying agent.

The operation principle of vortex granulator is the following.

A heat transfer agent is fed through the pipe into the device in the lower cylindrical section of the granulator. It flows to the vortex gas-distributing unit. The heat transfer agent is twisted around the vertical axis of the device and acquires a spiral motion. The vortex axisymmetrical flow of the heat transfer agent moves up the inner cone space towards the material. Simultaneously the fluid material (solution or fusion) is fed into the formed vortex flow of the heat transfer agent through the pipe in the upper part of the outing case into the spray unit. The fusion jet flows out of the spraying unit and is broken into the spheric granules. The created granules contact with axisymmetrical vortex flow of the heat transfer agent, get cool, are crystallized and come to the internal surface of the inner cone. Depending on the obtained size, granules are classified into the large and small fraction due to the whirl and axis velocity changes in the axisymmetrical vortex flow of the heat transfer agent heightwise of the inner cone. Small fraction granules are taken by the vortex flow of the heat transfer agent, move to the upper internal cone intersection and discharge from the active volume of the device through the annular space. In the annular space, the small fraction granules are moving down under the gravity force and get down to the lower intersection of the outing case. In the lower part of the outing case, these granules come to the depression zone. It is formed around the gas flow jet, which is fed through the pipe in the central part of the granulator (it is not shown on the scheme). Granules are sucked by this jet and are thrown to the central part of the inner cone workspace into the vortex weighted layer core. Fusion, that falls on the surface of the small granules, is crystallized. Therefore, the size of the granules increases. The large fraction does not leave the workspace of the device, and granules circulate in the inner cone and move down along its intersection, as far as they are growing and increasing. When the intended size is achieved, granules fall down on the surface of the inner cone, pass through the vortex gas-distributing unit and are output from the device. The spent heat transfer agent is driven from the inner cone through the proper pipe.

The operation principle of the gravitational shelf dryer is the following.

The drying agent, which at first is evenly distributed over the intersection of the body and then rises upwards, is brought to the lower section of the device. Therefore, it passes some (calculated, in this case – three) perforated inclined inserts (shelves), then it is output from the upper section of the device. Together with the motion of the drying agent, the dispersed material, which is necessary to dry, is fed to the upper shelf of the body. During the counteraction with the drying agent flow, the dispersed material is heated and the small fraction is removed with a purpose to balance the weighted layer porosity on the upper inclined contact shelf. The length of the inclined contact shelf provides the residence time of the dispersed material, which promotes the complete heating of the material, separation of the small dispersed particles and removal of the unbound humidity from the surface layer of the dispersed material during the constant drying velocity. The dispersed material is gradually moving along the upper shelf, is output through its free end and comes to the middle shelf, during drying by the drying agent flow. As the dispersed material moves through the middle shelf, unbound humidity is further removed from the surface layer of the dispersed material during the constant drying velocity as a result of the counteraction with the drying agent flow. The dispersed material is gradually output through the free end of the shelf and reaches the lower shelf. As the dispersed material moved through the lower shelf, the bound humidity is removed from the depth of the material during the drying velocity decrease. The dispersed material is output from the device after the drying process.

This device may be used to dry granular materials, for granulation, capsulation of the mineral fertilizers granules. In order to obtain the final product with a low level of the small dispersed (fine) particles, the process should be carried out with the initial separation, which is implemented on the upper shelf

of the device. There are hydrodynamic conditions under which the small fraction of particles (with the size less than 1 mm) is removed from the basic material.

FUTURE RESEARCH DIRECTIONS

The obtained results of the research have to be used in the modeling of the main technological equipment in the granulation unit under conditions of the granules variable mass and their compressed motion. For this purpose, it is necessary to implement the modeling of the granule heating kinetics, its dehydration and establishment of the gas flow motion intensity influence on the mass exchange processes.

The objective for further investigations is to create the algorithm to export the results of the constructive calculations of the main technological equipment in the granulation unit into the solid modeling programs.

After exportation one supposes to form the model of devices, design and technological documentation for their production.

After the implementation of the original idea to create compact and mobile granulation units through using the multiple-use technology of the drying agent's potential, a scientific method to calculate moving fluidized bed devices will be investigated by the possibility of utilizing harmful substances and by the heat and energy recuperation.

The obtained results of the project will let us define the complex effect made by the hydro- and thermodynamic conditions of the granulation process on the efficiency of moisture removal from dispersed particles with special properties (porous ammonium nitrate, encapsulated fertilizers with organic shell etc).

CONCLUSION

Based on the analysis of the ways to obtain the granulated product in units with implementation of the directed fluidized bed of the dispersed particles, it was defined that today there are no reliable mechanisms which control the residence time of the dispersed particle in the workspace of the device for such methods. It made impossible to obtain the granulated product with given qualitative indices with minimum energy costs for this process.

Cluster Granulation Unit® enables to carry out the optimization calculation of the main technological equipment in the granulation unit at the stage of its design without the expensive multifactorial experiment. The software peculiarities also let to carry out the equipment changeover if the raw material features and the productivity of the unit are changed.

The results of the optimization calculation with the software products and cluster implementation let to provide:

- a minimum “hydrodynamic” residence time of the particle in the device, which will not exceed “thermodynamic” time (minimum time of particles dehydration to the normative index is determined by the dehydration kinetics laws, thermodynamic indices of the dehydration process);
- implementation of different temperature and humidity potential of the heat transfer agent in some sections in the devices;
- variety of the device construction;
- possibility to use the recirculation of the heat transfer agent.

The original methods of the equipment engineering calculation with the directed fluidized bed as a part to obtain the granulated products are found.

The main recommendations to improve the technological equipment construction of the granulation unit have been implemented in the new methods of granulation, drying and classification in the directed fluidized bed and in devices for their fulfilment, protected by the patents.

ACKNOWLEDGMENT

This research work had been supported by the Cultural and Educational Grant Agency of the Slovak Republic (KEGA), project No. KEGA 002TnUAD-4/2019 and by the Ministry of Science and Education of Ukraine under the project “Technological bases of multistage convective drying in small-sized devices with utilization and heat recovery units”, project No. 0120U100476.

KEY TERMS AND DEFINITIONS

Computational Model: A mathematical model in computational science that requires extensive computational resources to study the behaviour of a complex system by computer simulation.

Drying: A mass transfer process consisting of the removal of water or another solvent by evaporation from a solid.

Fluidised Bed: A physical phenomenon occurring when a quantity of a solid particulate substance (usually present in a holding vessel) is placed under appropriate conditions to cause a solid/fluid mixture to behave as a fluid.

Granulation: The act or process of forming into grains or granules.

Hydrodynamics: A branch of physics that deals with the motion of fluids (gases) and the forces acting on solid bodies immersed in fluids (gases) and in motion relative to them.

Navier-Stokes Equations: The equations that describe the motion of viscous fluid substance.

Reynolds-Averaged Navier-Stokes Equations: The time-averaged equations of motion for fluid flow.

INTRODUCTION

The human society is an inseparable part of nature and if we perceive it as complex and difficult to describe, this is a result of the capabilities of our consciousness. The needs of the society and the vital resources required for its existence are completely embedded in the aspects of the surrounding reality. The nowadays use of natural resources demands a more complex assessment approach that takes into account factors such as economic efficiency, social impact, environmental impact, etc. The manner in which we conceptualize and utilize these resources depends on the level of the collective and personal individual consciousness and its perfection. Different social groups perceive and use the natural resources with different aspect of intensity and different awareness. This determines the multiple aspects of the production processes in the process of objectives' multiattribute modeling and formation as well as in the control of these processes. Accounting for the social and group interests in the nature utilization processes have been analyzed by various contemporary authors (Farnsworth, 1983; Shukla & Dubey, 1997; Jungmeier, 2003).

In the literature are discussed different decisions making approaches, as the focus is on the different aspects of the group decision making as a response to the multiple aspects of the interests and needs of the various social strata representatives. In the considered approaches and methods it is sought to additionally account for the intensity of the social or group preferences and their combination in common relation. However, it is necessary to emphasize that measurement and comparison of preference intensities are mathematically permissible in the interval scale (Clark, 1990; Keeney & Raiffa, 1999; Jungmeier, 2003).

There are many investigations of the production processes and its modeling (Hotelling, 1931; Swallow, 1994, Clark, 1990). Widely known and discussed are the models for production management proposed and used by Canadian scientists Clark and Munro (Clark & Munro, 1975). Both types – the exhaustive and renewable production were considered. Clark's models aiming at optimal resource use have been applied to fishing industry in Canada and mining enterprise, but they can also be applied to other branches of the economy and human activity such as agriculture, mining, logging, ecology, etc (Clark, Clarke & Munro, 1979). As a leading scientist in the theory of non-smooth optimization, Clarke has made a brilliant analysis of the optimal control under such modeling and has determined a strategy for finding this control (Clarke, 1983). However, there remains the question of accounting for and including social, economic and other human factors as an extension to this modeling. In our view this can be achieved by using measurement theory and utility and multiattribute utility theory (Fishburn, 1970; Pfanzagl, 1971; Keeney & Raiffa, 1999).

In the present chapter we will consider value based control of logging process with jointly accounted for complex social, ecological and economic factors in the modeling and control. Cases of renewable natural resources are considered including economic efficiency and social effect for the population.

DOI: 10.4018/978-1-7998-3479-3.ch089

The new element is taking into account the social impact on the population, such as pay, ecological effects such as biodiversity and their combination with economic efficiency in logging. This is achieved by constructing a multifactor utility function which under the different control models is used as an objective function or as a part of the differential equation describing the production process. The utility function is constructed based on the preferences of biologist expert and reflects his attitudes with respect to the considered production – in this case logging (Lyubenova et al, 2015). Such utility function can be constructed for every stakeholder: government, business, ecologists, or all of them combined in a single multifactor utility function.

BACKGROUND

In ordinal or ranked scale it is possible to search for a common conforming relation only in the same scale. Under the same, in essence, ranked approach there appears the so called Arrow's paradox (Ekeland, 1983). For this class of problem and on that level of measurement the most appropriate mathematical solution is the Kemeny-Snell's median (Litvak, 1982). However, finding it requires "branch and bound" type algorithms and this makes these algorithms difficult to use in practice. If a higher scale for measurement of the preferences is taken, such as the interval, there still remains the question for the respective mathematical validity and availability of appropriate theory and implemented algorithms.

In our view, the most mathematically founded is the approach of utility theory and multiattribute utility theory (Keeney & Raiffa, 1999; Pavlov & Andreev, 2013). Their proper use permits the most complete inclusion of the mathematical and computational power in the process of multifactor modeling and the control of natural exhaustive or renewable resources. The measurement scale for the utility function is the interval scale which allows for exact assessment and comparisons of the expressed human preferences and their intensity with respect to the production process and different aspects of it (Fishburn, 1970; Pfanzagl, 1971). In fact, the utility function is an analytical representation of the preferences in the temperature or interval scale. From conceptual point of view, when assessing utility it is necessary to account for real processes such as inaccuracy in the expressed preferences, errors, information uncertainty, etc. All of that places higher requirements to the process of assessment and measurement of the preferences and their analytical representation as utility. Due to this reason it has been chosen to use the approach of measurement theory combined with the theory of stochastic programming for the assessment and practical implementation of the utility and preferences in practice (Pavlov, 2005; Pavlov & Andreev, 2013).

FOREST SYSTEM, PREFERENCES AND UTILITY EVALUATION

In preceding years, a multiattribute utility function has been built, taking into account three important factors pertaining to a forest system (Lyubenova et al, 2015). The main objective and structure of the study was formulated by a qualified bio ecologist expert. On the basis of his preferences, the corresponding single-attribute utility functions were evaluated, and using the structure of the problem and the type of independence by utility among the factors, sub-objectives a multiattribute utility was constructed. This multi-attribute utility function could be used in a value based production model as objective function (Keeney, 1988). It is a polynomial approximation of von Neumann's utility and mathematically this polynomial approximation provides the standard for the application of utility in optimal control problems.

The expert analysis carried out led to accepting the following sub-objectives and the appropriate criteria, which adequately describe the main objective and are real, physically measured quantities:

- X_1 -factor (material services as volume of timber per hectare- economic effect) [10-300 m³.ha⁻¹];
- X_2 - factor (supporting services - ecological effect) [1-200 number of species per hectare];
- X_3 - factor (percentage of employed locals in the forestry sector - social effect) [1- 30%].

Independence by utility was found between the following factors in the process of investigation:

- X_2 from X_1 ; X_2 from X_3 ;
- X_3 from X_1 ; X_3 from X_2 ;

Utility independence of X_2 from the other two factors means the following. The DM's preferences between lotteries for x_2 , $x_2 \in X_2$ at different values of x_1 , $x_1 \in X_1$ and x_3 , $x_3 \in X_3$ do not change, suggesting utility independence of x_2 from the changes of other two factors. Whatever the reserves of wood in the forest ecosystem are and the employment of the population in the forestry sector may be different, but in any case the preferences are directed to the presence of a large species richness of the forest, i.e. great variety of species of trees, grasses, moss, lichen etc. that form the ecosystem and ensure its greater stability.

The preferences for gambles of the decision maker (DM) for x_3 at different values of x_1 and x_2 do not change, suggesting utility independence of x_3 from the changes of other two factors (Farquhar, 1984; Keeney & Raiffa, 1999). This means that whatever the reserves of wood are and at different species richness of the forest ecosystem, in any case, the preferences are aimed at the increasing of number of workers in the forestry sector. Using the theory for decomposition of a multi-attribute utility to simpler functions the following multi-attribute utility structure is determined (Keeney & Raiffa, 1999):

$$U(x_1; x_2; x_3) = k_1 U(x_1; x_2^0; x_3^0) + f_2(x_1) \times [U(x_1^0; x_2; x_3^0)] + \\ + f_3(x_1) \times [U(x_1^0; x_2^0; x_3)] + f_{23}(x_1) \times [U(x_1^0; x_2; x_3^0)] \times [U(x_1^0; x_2^0; x_3)],$$

where $U(x_1^0; x_2^0; x_3^0) = 0$ and $U(x_1^*; x_2^*; x_3^*) = 1$.

In the formula above $X^0 = (x_1^0; x_2^0; x_3^0) = (10, 1, 1)$ and $X^* = (x_1^*; x_2^*; x_3^*) = (300, 200, 30)$. The functions f_2 , f_3 and f_{23} have the forms:

$$f_2(x_1) = U(x_1; x_2^*; x_3^0) - k_1 U(x_1; x_2^0; x_3^0), \\ f_3(x_1) = U(x_1; x_2^0; x_3^*) - k_1 U(x_1; x_2^0; x_3^0), \\ f_{23}(x_1) = U(x_1; x_2^*; x_3^*) - f_2(x_1) - U(x_1; x_2^0; x_3^*).$$

Each of these sixth functions was evaluated based on the DM's preferences. In the following figure (1) are shown utility functions $U(x_1; 132; x_3)$ and $U(x_1; 20; x_3)$.

The described value modeling is part of the Smart Forest Ecological Management System ForEco which is based on Open Data and FIWARE (Lyubenova et al, 2015).

For the sake of completeness, we will describe in short the algorithms for evaluating the utility functions u . Two sets are defined for stochastic machine learning approximation utility evaluation (Pavlov & Marinov, 2018).

Figure 1. Utility functions: A – 132 Species in the Forest; B – 20 Species in the Forest

$$A_u = \{(\alpha, x, y, z) / (\alpha u(x) + (1-\alpha)u(y)) > u(z)\},$$

$$B_u = \{(\alpha, x, y, z) / (\alpha u(x) + (1-\alpha)u(y)) < u(z)\}.$$

The approximation of the utility function is constructed by pattern recognition of the set A_u . The assessment process is a machine-learning approach based on the DM's preferences and the machine learning is a probabilistic pattern recognition procedure because $(A_u \cap B_u^c) \neq \emptyset$ and the utility evaluation is a stochastic approximation with noise (uncertainty) elimination (Pavlov & Andreev, 2013). The following presents the evaluation: DM compares the "lottery" $\langle x, y, \alpha \rangle$ with the simple alternative $z, z \in X$ ("better-", $f(x, y, z, \alpha) = 1$ ", "worse-", $f(x, y, z, \alpha) = -1$) or "can't answer or equivalent- $\sim$, $f(x, y, z, \alpha) = 0$ ". The discrete function $f(\cdot)$ denotes the qualitative DM's answer expressed as preference. This determine a learning, a training point $((x, y, z, \alpha), f(x, y, z, \alpha))$. The following recurrent stochastic algorithm constructs the utility polynomial approximation based on a finit set of learning points:

$$u(x) = \sum_i c_i \Phi_i(x),$$

$$c_i^{n+1} = c_i^n + \gamma_n \left[f(t^{n+1}) - \overline{(c^n, \Psi(t^{n+1}))} \right] \Psi_i(t^{n+1}),$$

$$\sum_n \gamma_n = +\infty, \sum_n \gamma_n^2 < +\infty, \forall n, \gamma_n > 0.$$

The notations are based on the structure of the set A_u : $t = (x, y, z, \alpha)$, $\psi_i(t) = \psi_i(x, y, z, \alpha) = \alpha \Phi_i(x) + (1-\alpha) \Phi_i(y) - \Phi_i(z)$, where $(\Phi_i(x))$ is a family of polynomials. The line above the scalar product $\bar{v} = (c^n, \Psi(t))$ means: $(\bar{v} = 1)$, if $(v > 1)$, $(\bar{v} = -1)$ if $(v < -1)$, and $\bar{v} = v$ if $(-1 < v < 1)$. The coefficients c_i^n take part in the polynomial representation:

$$g^n(x) = \sum_{i=1}^n c_i^n \Phi_i(x), (c^n, \Psi(t)) = \alpha g^n(x) + (1-\alpha)g^n(y) - g^n(z),$$

$(c^n, \Psi(t)) = G^n(x, y, z, \alpha)$, where $(c^n, \Psi(t))$ is a scalar product.

The mathematical procedure describes the following assessment process. The learning points could be set randomly or with a pseudo random sequence. The expert relates intuitively the “lottery” (x, y, z, α) to the set A_u with probability $D_1(x, y, z, \alpha)$ or to the set B_u with probability $D_2(x, y, z, \alpha)$.

$f(x, y, z, \alpha) = D_1(x, y, z, \alpha) + \zeta = 1$ if (x, y, z, α) is referred to A_u or

$f(x, y, z, \alpha) = D_2(x, y, z, \alpha) + \zeta = -1$ if (x, y, z, α) is referred to B_u .

The probabilities $D_1(x, y, z, \alpha)$ and $D_2(x, y, z, \alpha)$ are mathematical expectations of $f(\cdot)$ over A_u and B_u respectively:

$(D_1(x, y, z, \alpha) = M(f/x, y, z, \alpha))$ if $(M(f/x, y, z, \alpha) > 0)$,

$(D_2(x, y, z, \alpha) = (-)M(f/x, y, z, \alpha))$ if $(M(f/x, y, z, \alpha) < 0)$.

Let $D'(x, y, z, \alpha)$ is the random value:

$D'(x, y, z, \alpha) = D_1(x, y, z, \alpha)$ if $(M(f/x, y, z, \alpha) > 0)$;

$D'(x, y, z, \alpha) = (-D_2(x, y, z, \alpha))$ if $(M(f/x, y, z, \alpha) < 0)$;

$D'(x, y, z, \alpha) = 0$ if $(M(f/x, y, z, \alpha) = 0)$.

We approximate $D'(x, y, z, \alpha)$ by $G(x, y, z, \alpha) = (\alpha g(x) + (1-\alpha)g(y) - g(z))$. The coefficients c_i^n take part in the approximation of the function $G(x, y, z, \alpha)$ $G^n(x, y, z, \alpha) = (c^n, \Psi(t))$. The function $G^n(x, y, z, \alpha)$ is positive over A_u and negative over B_u depending on the degree of approximation of $D'(x, y, z, \alpha)$. The function $g_n(x)$ is the approximation of the utility function $u(\cdot)$ (Pavlov & Andreev, 2013). The utility $U(x, y, z)$ and the single attribute utility functions are normed between 0 and 1 and are measured in the interval scale. These facts permit determination of the coefficients involved in the multiattribute utility function (Keeney & Raiffa, 1999).

The coefficients in the utility formula are determined by comparisons of lotteries of the following type (Pavlov & Andreev, 2013):

$$\left\{ \begin{array}{c} U(x_1) \times \alpha \\ + \\ U(x_2) \times (1-\alpha) \end{array} \right\} \begin{array}{c} > \\ \approx \\ < \end{array} U(x_3).$$

With $U(\cdot)$ is noted the utility function. The values x_1 , x_2 and x_3 are fixed and is fulfilled the following $(x_1 \uparrow x_3 \uparrow x_2)$ [8, 14]. The questions to the DM are like lotteries in which we vary only the probability $\alpha \in [0, 1]$. The stochastic procedure is of the type of Robins-Monro but the convergence is much quicker.

The procedure is the following. Let's α is a uniformly distributed random value in $[0, 1]$. We define the following random vector $\chi = (\eta_1, \eta_2, \eta_3)$, where:

- a) If $\{\}$ $\Rightarrow \chi = (\eta_1 = 1, \eta_2 = 0, \eta_3 = 0)$;
- b) If $\{\}$ $\Rightarrow \chi = (\eta_1 = 0, \eta_2 = 0, \eta_3 = 1)$;
- c) If indiscernibility $(\approx) \Rightarrow \chi = (\eta_1 = 0, \eta_2 = 1, \eta_3 = 0)$.

Let χ^n is a learning sequence of independent random values with equal to χ distribution. The stochastic recurrent procedure is the following:

$$(\lambda_1^{n+1}, \lambda_2^{n+1}, \lambda_3^{n+1}) = \Pr_P [(\lambda_1^n, \lambda_2^n, \lambda_3^n) + \gamma_n ((\eta_1^n, \eta_2^n, \eta_3^n) - (\lambda_1^n, \lambda_2^n, \lambda_3^n))],$$

$$\sum_1^\infty \gamma_n = \infty, \quad \sum_1^\infty \gamma_n^2 < \infty, \quad \gamma_n \geq 0, \forall n \in N, \text{ for example } \gamma_n = \frac{1}{(n+1)} \text{ with initial point is } 0.$$

The notation $\Pr_P$ has the meaning of projection over the set:

$$P = \{(\lambda_1, \lambda_2, \lambda_3) / \lambda_1 \geq 0, \lambda_2 \geq 0, \lambda_3 \geq 0, \lambda_1 + \lambda_2 + \lambda_3 = 1\}.$$

The searched value is determined in the end as the following:

$$U(x_3) = U(x_2) + (\lambda_1 + \lambda_2/2)(U(x_1) - U(x_2)).$$

The completed stochastically utility evaluation theory is exposed in the monographs (Pavlov & Andreev, 2013).

RENOUVABLE PRODUCTION MODELING AND EFFECTIVE FOREST MANAGEMENT

As noted in the introduction, the Clark and Munro models will be analyzed (Clark & Munro, 1975; Clark, Clarke & Munro, 1979). These models are used in the Canadian fishing industry and have been discussed multiple times by other scientists. The model in an abridged version has the form:

$$\begin{aligned} \dot{y} &= F(y) - qyK, \\ F(y) &= r(y(\theta - y)). \end{aligned}$$

In the above formula q , r , and θ are constants ($q=0.7$, $r=1.1$, $\theta=1$). With (y) is denoted the available renewable natural resource (timber per hectare- X_1), and with K we mention the funds invested in the logging (employed locals in the forestry sector- X_3). Such models are used and could be used in other areas of activity where the resources are renewable (Jungmeier, 2003). It is obvious that equilibrium in the forest system occurs when the derivative of the quantity of wood (the derivative of y) is zero. In the

Clark's model the optimization criterion is the maximum profit. This does not, however, take into account the social impact of production on the population as well as the ecological conditions at the moment. These factors could be reported by including in an integral (objective function) a multi-attribute utility function and directed it at the maximum. The goal is to maximize the integral:

$$J = \int_0^T U(y, K)(py - c)K dt .$$

In this formula $U(y, k)$ is the utility $U(x_1; 132; x_3)$, (p) and (c) are constants ($p=1.3$, $c=0.31$), and T is the end of the production period. The constant (p) reflects the market price of the wood and the constant (c) reflects its procurement cost. The problem thus defined is an optimal control problem. The control input are the money- the fund K invested in the wood industry.

In the Clark-Munro's model in place of utility is introduced an exponential function, which varies with time. This reflects the devaluation of capital in the time. A constant could be set for shorter periods of investigation. The inclusion of the utility function as a quantity under the integral allows the social and environmental factors to be accounted for by it. When choosing an optimal solution about the production, these factors will influence the solution depending on the type of the utility function. A solution based on the principle of maximum of Pontryagin may be sought (Pontryagin et al, 1964; Alekseev et al, 1979; Clarke, 1983; Gabasov & Kirilova 1981). The necessary conditions for optimality following the Pontryagin's maximum principle are the arguments that maximize the Hamiltonian:

$$H(T, \psi, y_{opt}, K_{opt}) = \max_k [\psi(F(y) - qyK) + U(y, K)(py - c)K], \quad 0 \leq K \leq K_{max} .$$

With $\Psi(\cdot)$ is noted an auxiliary covector-function $\psi(t)$, subject to the adjoint (linear) differential equation:

$$\dot{\psi} = - \frac{\partial H(T, \psi, y_{opt}, K_{opt})}{\partial y} .$$

For autonomous systems, as in this paper, is performed

$$\max_K H(T, \psi, y, K) = h, \quad h \text{ is a constant.}$$

The type of optimal control is determined by the following manifold:

$$M(y, K, \psi) = (U(y, K)(py - c) - \psi qy)K = 0.$$

The optimal control K is be determined by the manifold as follows:

$$M(y, K, \psi) > 0 \Rightarrow K = K_{max} ,$$

$$M(y, K, \psi) < 0 \Rightarrow K = 0.$$

Figure 2. Optimal production conditions: A – Equilibrium point; B – Objective Utility function

Thus defined the control problem defines “chattering control” or “bang-bang control”. Obviously in the logging for a period of several years this is unacceptable. It is impossible for instance to have six months of logging and subsequently six months of total forest recovery. Such management could be acceptable in fisheries or in agriculture for some renewable resources. A possibility is to explore the manifold $M(y, K, \psi) = 0$ and determine the renewable natural resource y as function of the input K and hence the derivative of y as function of K , derivative of K and derivative of y . Conversely, this will allow determination of the control K as a function of y and the derivative of y . Of course, if a solution is found. This control guarantees a sliding mode on the manifold. Such a sliding on the manifold will move the system to an optimal equilibrium point or an optimal periodic mode, depending on the type of the used utility function. The fed-back control could permit the autonomous system to remain on the manifold. The beginning point will determine the moment, crosses the manifold. After this moment the system will stay on the manifold. All of the discussed above is possible only for autonomous systems and without taking into account the effect of capital devaluation.

However, the availability of a multi-attribute utility function allows another possibility, another “good” solution with simpler calculations. In the literary sources are discussed steady states that are optimal for economic reasons (Clark, Clarke & Munro, 1979). We can approach the problem in the same way and look for a state of equilibrium that determines the maximum of the integral criterion J . The maximum of the function under the integral determines an equilibrium point as steady state possibility:

$$\begin{aligned}\Phi(y) &= U(y, K)(py - c)K \\ &= U(y, \frac{F(y)}{qy})(py - c)\frac{F(y)}{qy}.\end{aligned}$$

In the expression above the control K is replaced by a formula which is determined by the differential equation which described the renewable natural resource y assuming the derivative zero. The function $\Phi(y)$ and the optimal point (y^*, K^*) are shown in Figure 2a. In figure 2b is shown the utility function $U(x_1; 132; x_2)$ and the equilibrium point (y^*, K^*) . The location of this optimal point is marked with stars.

The differential equation that describe the dynamic of y determines the minimal time to attain the equilibrium, starting from any initial position (y_n, K_n) . If y_n is less than y^* ($y_n < y^*$), it is obviously necessary to let nature return to state y^* . This determines $K=0$. Conversely, if y_n is greater than y^* ($y_n >$

y^*), then the control input is maintained maximum ($K = K_{\max}$) until the equilibrium point (y^*, K^*) is reached. In this manner, good production parameters can be identified which take into account the complex social and environmental factors in logging. We need to clarify that this is not the mathematically accurate optimal control. The optimal solution generally requires a mathematical study in details of the manifold $M(y, K, \psi) = 0$ described above.

We can approach this problem in a different way in order to avoid the chattering control or the exploration of the sliding manifold. The optimization problem could be described as a Meyer's problem (Clarke, 1983; Alekseev et al, 1979; Gabasov & Kirilova 1981). For this purpose, we determine the control K by the differential equation which described the renewable natural resource y and its derivative:

$$K = \Phi(y, \dot{y}) = \frac{F(y) - \dot{y}}{qy},$$

where $F(y) = ry(\theta - y)$.

In the optimal control problem the initial conditions are known and are as follows: $y: [0, T] \rightarrow \mathbf{R}$, with initial conditions $y(0)$ and $\dot{y}(0)$. These two initial conditions determine exactly the control K . It is need one additional variable s , $s(0) = 0$ and it is additionally set a new restriction:

$$\phi(y, s, \dot{y}, \dot{s}) = -\dot{s} - U(y, \Phi(y, \dot{y}))(py - c)\Phi(y, \dot{y}) \leq 0.$$

The above formula includes the utility function and we underline once again that the utility function in this form takes into account the economic and social effect of the state of the forest system in a fixed biodiversity.

A new optimization problem will be defined. The new objective functional is $f(s, y) = s$. The optimization problem is reformulated as minimization of $f(s(T), y(T)) = s(T)$, subject to the above restriction:

$$\begin{aligned} \min s(T), \\ \dot{y} &= F(y) - qyK, \\ F(y) &= r(y(\theta - y)), \\ \phi(y, s, \dot{y}, \dot{s}) &\leq 0. \end{aligned}$$

Careful analysis shows that the optimal problem so defined is equivalent to the initial optimization problem. The equivalent mathematical formulations are as follows:

$\max J,$

$$\text{where } J = \int_0^T U(y, \frac{F(y) - \dot{y}}{qy})(py - c)\Phi(y, \dot{y})dt,$$

$$\dot{y} = F(y) - qyK,$$

$$F(y) = r(y(\theta - y)),$$

$$\phi(y, s, \dot{y}, \dot{s}) \leq 0.$$

The following mathematical result is used for the solution of this optimal problem. Let the continuous by parts curve $y(\cdot)$ is a weak local minimum in Meyer's problem and satisfy the regularity conditions described in the Clarke's monograph (Clarke, 1983). Then there is a curve $p(t)$, a measurable function $\lambda: [0, T] \rightarrow \mathbb{R}$ and a constant λ_0 equal to 0 or 1 for which the following is satisfied:

$$\begin{bmatrix} \dot{p}(t) \\ p(t) \end{bmatrix} \in \lambda(t) \partial \phi(y, s, \dot{y}, \dot{s}) \text{ almost everywhere (a.e.);}$$

$$\lambda(t) \leq 0 \text{ a.e., } \lambda(t) = 0 \text{ when } \phi(y, s, \dot{y}, \dot{s}) < 0;$$

$$-p(T) \in \lambda_0 \partial f(s(T), y(T));$$

$$\|p(\cdot)\| + \lambda_0 \neq 0.$$

The mathematical expressions for $p(t)$ and its derivative $\dot{p}(t)$ are determined with the use of the above mathematical result. The time derivative of $p(t)$ is compared with the already determined mathematical expression for $\dot{p}(t)$. This comparison permits the determination of the second derivative $\ddot{y}$ as a function of y and $\dot{y}$. In this way, the derivate $\dot{K}$ of the control input K is determined at any moment. Then the optimal control is could be obtained as a solution of the following differential equation:

$$\dot{y} = r(y(\theta - y)) - qyK,$$

$$\dot{K} = -\frac{\ddot{y}}{qy} - \frac{r\dot{y}}{y} + \frac{1}{q} \left(\frac{\dot{y}}{y} \right)^2,$$

$$0 \leq K \leq K_{\max}.$$

For completeness of the exposition we will give the formula for the second derivative $\ddot{y}$. In the formulas below, we mark with U the utility function:

$$U(y, K) = U(y, \frac{F(y) - \dot{y}}{qy}).$$

Figure 3. Optimal production control: A – Optimal control; B – Optimal trajectories in connection with Utility function

The second derivative is described by the following formula:

$$B(y, \dot{y}) = \left[\frac{\partial U}{\partial y} \frac{F(y)}{qy} + \frac{\partial U}{\partial K} \left(\frac{-r}{q} \right) \frac{F(y)}{qy} - U \frac{p}{(c - py)} \frac{F(y)}{qy} + \frac{\partial U}{\partial K} \frac{F(y)}{q^2 y^3} \dot{y} + U \left(\frac{-r}{q} \right) \right],$$

$$\Gamma(y, \dot{y}) = \left[\frac{\partial^2 U}{\partial K \partial y} \cdot \frac{(-1)}{qy} + \frac{\partial^2 U}{\partial K^2} \frac{r}{q^2 y} - \frac{\partial U}{\partial K} \frac{p}{(c - py)} \frac{(-1)}{qy} + \frac{\partial U}{\partial K} \frac{1}{qy^2} \right] \dot{y} + \frac{\partial^2 U}{\partial K^2} \left(\frac{-1}{q^2 y^3} \right) (\dot{y})^2,$$

$$\Theta(y) = \left[\frac{\partial^2 U}{\partial K^2} + \frac{\partial U}{\partial K} \right] \frac{1}{(qy)^2},$$

$$\ddot{y} = \frac{B(y, \dot{y}) - \Gamma(y, \dot{y})}{\Theta(y)}.$$

It is necessary to be careful with the choice of the differential solver due to the peculiarities of Meyer's problem. At low values of the derivatives, the calculations are slow. The second derivative formulation of $\ddot{y}$ is quite large and heavy. But the discussed decision procedure allows anyone interested to find them. Only standard derivative calculations and enthusiasm are required. It is emphasized that the utility function $U(y; 132; K)$, has a polynomial mathematical description and it participates in these mathematical formulations, including with its own partial derivatives on the corresponding variables. In figure 3a are shown three optimal control solutions starting from three different initial points. In the figure 3b are shown the optimal trajectories of these processes in connection with the utility function.

It is obvious that the time minimization control is close to the optimal control for some initial conditions. In this manner, good production parameters can be identified which take into account the complex social and environmental factors in logging.

This solution focuses attention on complex models and mathematically well-founded methods where the decision maker is represented through his preference as a value or utility function, being part of the

mathematical modeling process. In fact, it is a value-based design, an engineering strategy grounded on system analyses enabling multidisciplinary design optimization (Keeney, 1988; Collopy & Hollings, 2009).

DISCUSSIONS

We underline that in the place of the utility function is putted a constant in Clark and Munro's models. Under these conditions, the optimal problem cannot be defined as Meyer's optimal problem, due to some particularities of the renewable production model. For this case is made an excellent analyze by Clarke (Clark, Clarke & Munro, 1979; Clarke, 1983). The demonstrated solution is possible because of the inclusion of the analytic utility function and the possibilities to calculate the partial derivatives.

It is seen that the DM's preferences representation as polynomial utility function allows being used the full power of optimal control theory in its modern form. Utilization of multiattribute utility functions in complex problems, taking into account complex social, economic, environmental, ecological and other factors permits a new value based modeling, value driven control and management synchronous with DM's preferences (Keeney, 1988; Ekeland, 1979). For some complex systems and problems, this is the only way for a good mathematical description.

These solutions allow good planning of logging processes when selecting the relevant forest parameters and wood prices. Whatever the semantic interpretation of the discussed models, the determination of optimal control follows one and the same mathematical procedures. That is to say, the model and utility representation can be set different semantics in different production conditions, but the mathematical procedure and solution remains the same. We repeat, this is partly due to the polynomial utility approximation.

CONCLUSION

The rational actions of the DM in complex forest processes are of great importance for good production results. The qualitative nature of man's evaluation and analysis is a limitation to this process. This imposes the need of developing specific approaches and methods for the analysis and evaluation of qualitative, conceptual information. Human values (utility) are the internal motivation for determining the goal and find out a good solution. One possible approach to the problem is the multiattribute utility approach. In that aspect, the program of actions of the DM towards the problem is a hierarchical decomposition of the considered goal. Preferences are expressed concerning the chosen goal and sub-objectives and value and utility functions are made that are later used in the standard mathematical processing.

The constructed multiattribute utility function reflects the DM preferences and attitudes toward the three forest factors, ecology, economic effect and social effect of the logging. In the renewable production model and exhaustible production model the utility function could be included in two different ways. The utility function is a part of the objective function in the renewable model, while in the exhaustible production model the utility function could be part of a differential equation. Such a value based modeling permits determination of optimal control and value driven management strategy in line with the DM's preferences regarding the multifactor problem.

In conclusion, we would like to point out that the model is actually a complex mathematical model of the kind "human-dynamic production", taking into account the complex social and economic characteristics of the timber production process.

KEY TERMS AND DEFINITIONS

Complexity: A condition of a system or situation integrated with some degree of order but with too many elements and relationships to be understood in a simple analytic or logical way. In the extreme, the complex system or situation is with multiple and diverse connections with dynamic and interdependent relationships, events, and processes.

Dynamic Model: Represents the behavior of an object over time. Dynamical systems theory is an area of mathematics used to describe the behavior of the complex dynamical systems, usually by employing differential equations or difference equations. When differential equations are employed, the theory is called continuous dynamical systems.

Model-Driven Decision-Making and Control: An emphasized access to and manipulation of a statistical, financial, optimization, or simulation model. It uses data and parameters provided by users to assist decision process in analyzing a situation.

Optimal Control: Is the process of determining *control* and state trajectories for a dynamic system over a period of time to minimize a performance index.

Utility Independence: An attribute A1 is utility-independent of attribute A2, if conditional preferences on lotteries on A1, given at a fixed value of A2, do not depend on that fixed point. The utility independence is not symmetrical.

Utility Theory: A normative approach to the issue of how people should rationally choose in conditions of uncertainty.

Value-Driven Design: A system engineering strategy, which enables multidisciplinary design optimization. It creates an environment for optimization by providing designers with a value function as objective or as part of the mathematical model.

Agriculture 4.0 and Bioeconomy: Strategies of the European Union and Germany to Promote the Agricultural Sector – Opportunities and Strains of Digitization and the Use of Bio-Based Innovations

10

Immo H. Wernicke

German Government (retired), Germany

INTRODUCTION

Agriculture 4.0 and Bioeconomy are new strategies of the European Union and the German Government for promoting Research and Development and the implementation of digital technologies and bio-based innovations in the agricultural sector. The programs upgrade the traditional Common Agricultural Policy and enlarge the legal and institutional framework of the *Acquis Communautaire*. Millions of agricultural holdings in Europe are encouraged to use biomass, renewable energies, digital innovations, and high tech machinery provided under the label of Industrie 4.0. The discussed strategies aim to achieve sustainable growth and competitiveness in agriculture, to secure self-sufficiency in food and energy production in Europe and to cover the Sustainable Development Goals of the United Nations. Both concepts provide opportunities to overcome the increasing demand for food by an exploding population. To be discussed are risks due to high investment costs, cyber crime, and poor public funds for improving the fragmented digital and energetic infrastructure. The improving of the official database is a precondition to get more information that is accurate on the impact of Agriculture 4.0 and Bioeconomy.

BACKGROUND

The term **Agriculture 4.0** is used as an official label of the 2020 strategic program of the European Commission (EC) and the German Government for promoting the agricultural sector, rural areas and the nutrition industries to achieve sustainable growth (EU Commission, 2018 a).

The term **Bioeconomy** is defined by the Directorate-General for Research and Innovation of the EC as a new economic system based on the sustainable use of renewable biological resources such as crops, forests, fish, animals and micro-organisms to produce food, materials and energy (European Commission, 2017).

Agriculture 4.0 is an innovative program for the benefit of the agricultural sector that refers to the Industrie 4.0 strategy of the EC and the German Government to foster the digitization of the Manufacturing Industries (Price Waterhouse, 2015). It goes back to the idea of the advisor to German Chancellor Angela Merkel Jeremy Rifkin (2015), who recommends a Digital Revolution in Europe also in the agricultural sector (Rossner, E. 2015). Digital innovations from the Information and Communications Technologies (ICT) sector including Start-ups and high tech machinery from the Manufacturing Industries are to be implemented in the complete supply chain from animal production and the use agricultural land to food

DOI: 10.4018/978-1-7998-3479-3.ch090

Source: Overview from different reports on Agriculture 4.0 by author

processing and distribution and finally to the selling to the consumers on cellular phone demand. **Figure 1** presents the main technologies of Agriculture 4.0.

The European Commission's Science and Knowledge Service (2016) being founded to evaluate the innovation program of the EC approves "New technologies and their adoption by EU farmers are key drivers in maintaining European agriculture competitive in a global world." Agriculture 4.0 is also connected to the Bioeconomy program that was launched by the EC in 2012 (EU Commission, Directorate-General for Research and Innovation, 2017). The EC Program Biotechnology and Life Sciences precedes the Bioeconomy concept as it was set up in 1982. The EC evaluates its former Biotechnology Strategy as "an important step towards a competitive and sustainable Knowledge Based Bio-Economy (KBBE)." The new strategy includes the traditional concept of Biotechnology, such as genes technology and all biotechnological applications across sectors in primary production, in industry and in the health sector described in detail by Patermann, C. and Aguilar, A. (2018).

As new components of the complex European and German institutional and legal system the Bioeconomy- and Agriculture 4.0-strategies have led to a multifold set of parliamentary decisions, regulations, funding and procurement programs, internet platforms, reviews, reports, staff working papers, working groups, manuals and other publications. The article focuses on the presentation and discussion of a few selected activities.

Generally said, these new strategies in agricultural politics supplement the already existing gigantic legal and institutional framework in Germany and in the EU laid down in the *Acquis Communautaire* that consists of about 100.000 pages covering the full scope of European legal issues. The new agricultural strategies of the EU and Germany are going well beyond the traditional Common Agricultural Policy (CAP), which is already providing about 50 Billion € as subsidies to the farmers in Europe every year and for decades (EU Commission, 2014 b).

Millions of agricultural holdings and family farms are being encouraged by the new concepts to make use of technical innovations, Bioeconomy, and renewable energies to achieve growth and competitive-

ness in agricultural production. The strategies are also addressed to academics, technical universities, and research institutes for receiving official funds for Research and Development (R&D) activities on these issues.

The concepts and their implied digital technologies have spread worldwide and influenced international agricultural politics, the media, and academic research. They became basic components of international fairs and put as topics of the agendas of international conferences, including the G 20 and the G7 meetings. Both concepts are complying with the recommendations of the FAO (2015), the Food and Agricultural Organization of the United Nations, and with the Sustainable Development Goals of the United Nations (2015). They seem to become a promising innovative agricultural policy also in developing countries for achieving worldwide sustainable growth in agriculture, forestry, in the nutrition industries and in rural areas also to tackle climate change and to overcome the increasing demand for food due to the increasing of world population. The FAO (2015, 2017) predicts about 9 billion people will need food and water in 2030.

OPPORTUNITIES AND STRAINS OF AGRICULTURE 4.0 AND BIOECONOMY

Opportunities for the Academia and Research Institutes

The new strategies provide many opportunities for the academia and research institutes. The EU Commission and the German Ministry of Education and Research (2011, 2014) are funding scientific institutes to implement the transformation from an oil-based to a bio-based industry. They also foster academic research on bio-based innovations for achieving sustainable economic growth in agriculture.

One of the new research projects is labeled as BioKompass. The Fraunhofer Institute Germany (2018) is charged to implement the project and to explore the transformation of the economy into a Bioeconomy. The German Research Center Juelich (2018) plays a key role, too, by using new techniques such as terrestrial systems for research on crop and plant production, and the Universities of Hohenheim and Vechta are specialized on master theses on these issues.

International High-level Summits on Agriculture and Bioeconomy in Berlin

The traditional international fair on agriculture in Berlin focuses many of its activities on both strategies. The Agricultural Ministry and the German Farmers Association (2015) have established a yearly international high-level conference on agricultural politics and put Bioeconomy as a topic on the agenda of the International Agriculture Ministers' Summit in Berlin in 2015. The German Minister of Food and Agriculture Schmidt (2015) initiated an international resolution, he accentuated "Bioeconomy will represent an opportunity for everyone and agricultural policy must go hand in hand with coherent economic, trade and energy policies - this applies to both national and global policies." Agricultural Ministers of 70 States and delegates of the FAO, the World Bank, and the EU-Commission have passed a resolution on Bioeconomy later put on the agenda of the G 20 and the G7 conferences.

The German Government has founded the German Bioeconomy Council (2018) that plays a key role in organizing the Global Bioeconomy Summits in Berlin: "Bioeconomy promotes distinct features of interest to several SDG (Sustainable Development Goals of the United Nations), including knowledge-based growth and jobs, the renewability of resources, resilience of ecosystems...". This international forum is a platform for information exchange between international experts and for discussing new policy strategies and initiatives from a global perspective. **Figure 2** presents the main technologies of Bioeconomy.

European Innovation Partnership for Agricultural Productivity and Sustainability

On the European level, the EU Commission launched the European Innovation Partnership for Agricultural productivity and Sustainability (EIP-AGRI) in 2012, preceding the two new strategies. It aims to foster a competitive and sustainable agriculture and forestry sector that “achieves more from less.” The EIP-AGRI contributes to ensuring a steady supply of food, feed, and biomaterials and a sustainable management of the essential natural resources on which farming and forestry depends. It brings together innovative farmers, holders, advisors, academics, researchers, and business managers and helps to build bridges between research and practice.

The European Technology Platforms (ETP) on Bioeconomy and Biomass

The EU Commission (2018 b) has also set up nine European Technology Platforms (ETPs) to foster Bioeconomy and biomass. The result of the collaboration between experts from the academia, industry, civil society organizations, farmers and forest owners have been published in the White Paper on the European Bioeconomy 2030. The White Paper of the EU Commission (2018 c) covers a large scope of issues like biomass, bio energy, and renewable energies like solar and wind energy. A basic technology outlined in the White Paper refers to the sustainable production and conversion of biomass into a variety of agricultural, industrial, and energetic products: food, health, fiber etc.

Renewable biomass encompasses any biological material (agriculture, forestry, and animal-based including fish) are to be used as a product in itself or as raw material. The White Paper also provides policy recommendations and covers a wide range of agricultural sectors – arable and livestock farming, forestry, food, aquaculture, the chemical industry, materials manufacturing and energy – to create a smart, sustainable, and inclusive European Bioeconomy.

The experts of the FAO, the OECD (2015) and the EU Commission (2018 d) have identified biomass as a prior growth factor in agriculture, as it is usable for the production of food, bio-plastics, transport fuels, electricity, heat, chemicals, and medicines.

The International Fair Agritechnica in Hanover Promotes Agriculture 4.0

The Agritechnica (2017), the international fair for agricultural machinery and industrial innovations in Hanover in Germany, functions as a key promoter of Agriculture 4.0 and Bioeconomy. The world's leading trade fair on farm machinery has become an international platform for the presentation of new technological developments in agriculture and for promoting negotiations between industrial exhibitors and managers of agricultural holdings and farmers. The German Agricultural Association (2015, 2017, and 2018) is one of the organizers of the fair that is presenting a wide range of innovations and technologies from the agricultural engineering industry and the Industrie 4.0 program, such as mobile machinery, hydraulic systems, engines, axles and drive technology, cabs, electronic systems, and ICT software. It offers a broad technical program including special shows, discussion forums inviting exhibitors, engineers, ICT experts, holding managers and farmers to discuss specific topics for future plant production.

The fair exhibits technological products, experience, and expertise on smart technologies to support farmers in practicing smart farming for a “green future.” Smart technologies are serving to reduce investment costs, allow better organizing specific jobs, reducing energy consumption, serving to protect soil, optimize nutrient and water use, and assisting to identify and treat pests and weeds. (Agritechnica, 2017)

Technologies of Agriculture 4.0 provided by Industrie 4.0

The EU Commission's Science and Knowledge Service (2016) accentuates that “New technologies and their adoption by EU farmers are key drivers in maintaining European agriculture competitive in a global world.” The European strategic concepts are backed up by large governmental funds and the public budget. The means focus support on the micro level to farms and farmers, cooperatives and S+M companies. (EU Commission, 2016)

The ongoing technical progress in the industrial world supplies high-tech agricultural machinery and equipment, such as drones and unmanned helicopters and seems to approve the vision of Rifkin, J. (2015) of a future digital world based on renewable energy. The nutrition industries and the logistics sector will also benefit from the new Cyber Physical System, which “stands for a demand driven decentralized and intelligent production process.” The digitizing of the transport and storing system in the complete supply chain might overcome the crucial challenge of managing waste of agricultural products and food. (McClelland, J. 2015)

Robotics, Drones and Unmanned Helicopters, Radio Controlled Agricultural Machinery

Robotics and Robots belong to the basic technologies of the German Industrie 4.0 – strategy presented at the International Fair on Industries Hanover (2015, 2018). Robots can take over many activities traditionally done by the farmers or their workforce. Digitization also allows a large scale seeding. German farmers interviewed by the Boston Consulting Group (2015) perform harvesting of fragmented farmland of small holders by setting up “virtually consolidated” plots of small farmers across field boundaries.

Drones and unmanned helicopters, first developed for military use, are useful innovative technical instruments for the agricultural sector. Being equipped with digital cameras and sensor techniques drones and unmanned helicopters enable the monitoring of the surface of arable land and the geological conditions of soil. The use of drones and unmanned helicopters allows a continuous monitoring of fruit growing and crops plantations, too. As part of digitized early warning systems, drones and unmanned helicopters can reveal threats on crops and can provide more accurate and reliable estimates of future yield of harvests. (Van Vark, C. 2016)

These digital technologies enable farmers for a more efficient and precise use of seeds, fertilizer and pesticides for crop plantation. **Precision farming** has become a prior topic of international discussion and negotiations. In January 2019 at the International Agricultural Ministers Conference in Berlin the German Agricultural Minister, Klöckner, J. (2019) has promoted the digitization of the agricultural sector internationally: “The decision to establish an international Digital Council is a breakthrough!” **Figure 3** presents digital equipment for precision farming.

Figure 3. Digital equipment for precision farming at International Green Week 2019

Source: Photo taken at International Green Week Berlin Germany 2019

Radio controlled agricultural high tech machinery such as harvesters run by bio fuel or solar energy make seeding, plowing and harvesting more efficient. Livestock farmers and holdings can profit from digitally controlled automatic feeding and milking machines for cattle. (Bailey P. 2013)

Smart Technologies for use by Smaller Holdings in Agriculture

Smart technologies for the crop production process enable to better organize labor input and energy consumption, they save costs, help protect the soil, optimize nutrient and water use, or help to identify and treat pests and weeds more efficiently. The fair Agritechnica (2017) presents also different smart technologies at each stage of the crop-production process to improve working conditions of farmers. Tillage technologies are combining tillage with fertilizer application (side dressing), strip till will combine deep tillage with no-till, and better straw management is enabled after harvest. Seeding technologies are combining seeding and fertilizing, and site-specific seed densities. Fertilizer technologies improve fertilizer planning, soil testing, and enable sensor-based fertilizing, technologies on plant protection like sensors, drones and satellites enable improved forecasts, pest detection and the reduction of spray rates and a single-plant treatment. Harvest technologies including sensors, drones, and satellites can reduce harvest losses, detect optimal harvest times, improve logistics, and better residue management. Software and data management systems provide field catalogues combined with forecast models or decision support models. (AGCO, 2019)

Farms and Agricultural Holdings as Smart Factories

Digital innovations in container systems developed by Industrie 4.0 provide farmers new opportunities to set up “mobile intelligent factories” for the processing of food. Both the agricultural sector and the nutrition industries might profit from the new container system for more mobility in farming and food processing. Additive Manufacturing allows an ICT supported small-scale production by the use of the 3D-Printer-Technology. All pulverized solid materials, metals, and plastics are producible by biomass, and they can be processed by the 3D-Printer-Technology. Farmers will be enabled to produce their technical equipment and to spare parts of their agricultural machinery in containers at their premises. Internet access provided by broadband techniques or mobile satellite systems will improve the farmer’s management activities for marketing and sales promotion (Agritechnica, 2017).

The digital revolution enables farmers to become shareholders of companies of the nutrition industries or of transport and logistics companies. The performance of the nutrition industries can benefit significantly through the digitization of food processing, too. The establishment of sharing models and the building up of cooperatives make these innovative techniques also affordable to small holders.

Renewable Energies Provide Opportunities for Farmers and Agricultural Holdings

The German Ministry for Economic Affairs and Energy (2015) and the European Union have passed their new Strategy 2020 on renewable energies. The strategy promotes the transformation from nuclear and fossil energies to a mix of the full scope of renewable energies, such as wind energy, hydropower, geothermal energy, photovoltaic energy, solar thermal power plants and storage technology, biogas, bio fuels and solid biomass. Renewable energies can create income for farmers operating wind and solar parks, can achieve a reduction of costs in the agricultural sector, might tackle climate change, and can achieve energy security. Decentralized solutions of energy supply encourage farmers and agricultural holdings to cooperate with local networks, power stations, and locally operating management companies for additional income and cost reduction.

Digital Technologies from Urbanized Areas Used in Rural Areas

Agriculture, rural development, and urbanization are interconnected and build up the driving force for technological progress, as the German Minister for Cooperation and Development, Mueller (2016) has pointed out at the UN Habitat conference in Berlin. Digital startups from universities, research institutes, and R&D departments of large industrial enterprises located in cities have initiated the digital revolution in Europe. Farmers benefit from large-scale production by the manufacturing industries. The digitalization of the whole supply chain including the logistics sector allow a more efficient distribution of agricultural products and food from rural areas, processed in urbanized areas to the consumers living in the cities.

Agriculture 4.0 and Bioeconomy Provide Tools for Small Holders in Developing Countries

The concepts Agriculture 4.0 and Bioeconomy might be useful also in developing countries to overcome malnutrition, to achieve the Sustainable Development Goals of the United Nations and to overcome the expected decrease of arable land due to the increase of urbanization. Digital innovations for agricultural machinery and facilities, Bioeconomy and the use of Biomass and renewable energies in agricultural production, crops plantation, live stock farming, marketing, and sales set up basic elements of the new Common Agricultural Policy of the EU (EU Commission, 2014 a, b).

Large-scale farms in developing countries can already profit from the use of modern high-tech machinery, ICT-equipment, the Geographical Information System (GIS) and earn income by large-scale wind and solar parks and Biomass power stations. The poor financial situation of family farms, small-holdings, and subsistence farming needs international support to make use of the Agriculture 4.0 and Bioeconomy strategies. High costs for implementing Agriculture 4.0 technologies enforce small holders to set up cooperatives and to set up concepts of sharing machinery, equipment, and premises and putting together plots of land. Cooperatives are a promising legal frame for small holders to get access to financial means and to profit from Bioeconomy, renewable energies, and the achievements of Agriculture 4.0. Inefficient subsistence farming and civil war problems are threats for a successful agricultural policy in developing countries. The expected decrease of arable land and forestry by urbanization is a further threat on future growth and for tackling the pace of population increase (FAO, 2015, G 7 Summit, 2016).

Fragmented Digital and Energetic Infrastructure and Financial Strains on Agricultural Holdings

The use of high-tech-systems, ICT-systems, and of digitally equipped machinery in agricultural production needs high speed 5 G digital networks and a functioning energetic infrastructure in all countries, worldwide. Especially rural areas in Germany and Europe face a fragmented digital and energetic infrastructure as crucial burden to the bio economic transformation of traditional agricultural production to smart farming. The gap between increasing prices of machinery, equipment, and services and decreasing prices for food sales is a financial strain for the agricultural sector. Thus, high investment costs and financial risks for implementing the Agriculture 4.0 and Bioeconomy concepts are a crucial strain on agriculture (Torrìsi, G. 2009). Strains on the agricultural sector by the digitization of agricultural production and the use of the internet are also to be feared by cyber crime and by the hacking of digital systems and data banks.

Impact of Agriculture 4.0 and Bioeconomy

Official data and results on the impact of the new agricultural policy, the multifold official programs and of public procurement activities on the economy and the agricultural sector are poor, as official statistics do not adequately cover the basic aspects of Bioeconomy and Agriculture 4.0 covering the risks, financial strains and benefits from the transformation. The state of the transformation from traditional farming to digitalized agricultural production and to the use of Bioeconomy and renewable energies is not yet transparent. A few reports on survey results conducted by consulting groups and company associations approve that about 10-15% of SMEs in manufacturing industries in Germany have implemented the concept Industry 4.0, whereas the majority of farmers in Europe are at the very beginning of Rifkin's digital revolution (Boston Consulting Group, 2015). The poor official database is also criticized by the Thuenen Institute (2018), which has set up a Bioeconomy Monitoring System. The institute admits: "Even the question of the actual state of bio-economy in Germany could not satisfactorily be answered, as detailed data do often not exist."

SOLUTIONS AND RECOMMENDATIONS

The use of High-tech-systems and ICT-systems in agricultural production and food processing could enable Millions of farmers and manager of holdings and the nutrition industries to save of resources and input, for overcoming transformation costs and risks. Especially for small holders and for family farms the sharing of High tech agricultural machinery and equipment and the founding of cooperatives might strengthen their financial capacities and support to tackle financial strains and risks of investment in implementing digital and bio-based innovations. Enterprises of the machine manufacturing industries can save resources by improving recycling procedures. This will significantly reduce costs of agricultural production and the use of innovative machinery. The public sector is to invest more in digital and energetic infrastructures especially in rural areas. More public and private funding is necessary, and the release of "green loans" and "green equity funds" and temporary tax reliefs might lead to solutions.

The official database is still inadequate. To analyze the impact of the new strategies and to draft comprehensive progress reports the official database is to be improved. Governments are proposed to provide more official macro- and microeconomic information about the benefits and risks of the transformation from traditional farming to smart and digitized farming. Statistical institutes and the agricultural ministries are to improve their standard data collections. Governments are to increase expenditures for restructuring the fragmented digital and energetic infrastructures especially in rural areas for the benefit of the agricultural sector.

FUTURE REASEARCH DIRECTIONS

The world is staying at the beginning of the digital revolution. More research is needed on the micro- and macro-economic level. For comprehensive and accurate analyses and reports on the impact of the implementation of the strategies Agriculture 4.0, Bioeconomy, including renewable energies, in the agricultural sector accurate official databases are a precondition. Agricultural Ministries and Statistical Institutes are to set up accurate databases to cover the transformation from the traditional economy to a digitized agricultural sector. Official data have to cover the benefits and the costs of investment for digital

and bio-based innovations, business results on production, income, profitability, risks, and employment, and the financial needs of agricultural holdings and family farms for investment in digitization.

CONCLUSION

The new strategies Agriculture 4.0 and Bioeconomy of the German Government and the EU Commission are promotion programs to foster digital technologies and bio-based innovations by funding R&D. The discussed programs provide also opportunities for farmers and agricultural holdings to make use of digital technologies, high tech machinery, bio-based innovations, and renewable energies.

Millions of agricultural holdings in Europe are encouraged to use biomass, renewable energies, digital innovations, and high tech machinery provided by the industrial and digital sectors under the label of Industrie 4.0. The officially funded programs, platforms, fairs, and conferences aim to achieve more efficiency and sustainable growth in the agricultural sector for securing self-sufficiency in food and energy production in Europe and to cover the Sustainable Development Goals of the United Nations. Both concepts may be useful to developing countries to win the race against exploding population and the sharp increase of demand for food.

Threats on implementing the digitization in the agricultural sector are to be feared by the risks of high investment costs, cyber crime, and by poor public budgets for improving the fragmented digital and energetic infrastructures.

The world is staying at the beginning of the digital revolution. Up to date these digital innovations have not yet been implemented by the majority of companies and holdings in the industrial and agricultural sectors. Due to poor official statistics on micro- and macro-level, only inaccurate reports on the impact of the digital and bio-based technologies of Agriculture 4.0 and Bioeconomy on holdings in the agricultural sector are available. Official databases covering of the risks, benefits, growth, and competitiveness during the digital transformation need significant improvements.

KEY TERMS AND DEFINITIONS

Agriculture 4.0: A strategic concept to implement digital technologies and high-tech machineries and equipment in the agricultural sector and in the nutrition industries.

Bio Energy: Is set up by biogas, bio-fuel, etc.

Bio Mass: Encompasses any biological material from agriculture and forestry and includes animal-based material as a product in itself or to be used as raw material for renewable energy such as bio gas or even 3 D printing.

Bioeconomy: An official strategy to implement a new economic system based on the sustainable use of biological resources and is including the traditional concept of “biotechnology.”

Precision Farming: The use of digital equipment enabling farmers for a more efficient and precise use of seeds, fertilizer, and pesticides for crop plantation.

Renewable Energies: Are defined by solar, photovoltaic, wind, bio energy, etc.

Overview of Solid Waste Management of Healthcare and Related Organisations

INTRODUCTION

Medical solid waste is any solid waste which is generated in the diagnosis, treatment (provision of medical services), or immunization of human beings or animals, in research pertaining thereto, or in the production or testing of biological. Medical waste (MW) is classified by the World Health Organization (WHO) as “waste that is generated in the diagnosis, treatment or immunization of human beings or animals”. As defined by WHO (2014), the term health-care waste includes all the waste generated within healthcare facilities, research centres and laboratories related to medical procedures. It also includes waste produced in the course of health care undertaken in the home. Management of medical (healthcare) waste is an integral part of infection control and hygiene programs in healthcare settings. These settings are a major contributor to community acquired infection, as they produce large amounts of biomedical waste. Biomedical waste can be categorized based on the risk of causing injury and/or infection during handling and disposal. Wastes targeted for precautions during handling and disposal include sharps (needles or scalpel blades), pathological wastes (anatomical body parts, microbiology cultures and blood samples) and infectious wastes (items contaminated with body fluids and discharges such as dressing, catheters and IV. lines). Other wastes generated in healthcare settings include radioactive wastes, mercury containing instruments and polyvinyl chloride (PVC) plastics. These are among the most environmentally sensitive by-products of healthcare (Remy, 2001). World Health Organization (WHO) stated that 85% of hospital wastes are actually non-hazardous, around 10% are infectious and around 5% are non-infectious but hazardous wastes. In the USA, about 15% of hospital waste is regulated as infectious waste. In India this could range from 15% to 35% depending on the total amount of waste generated (Glenn and Garwal, 1999; Soliman and Ahmed, 2007).

Healthcare waste products should be considered as a reservoir of pathogenic microorganisms, which can cause contamination and give rise to infection. If waste is inadequately managed, these microorganisms can be transmitted by direct contact, in the air or by a variety of vectors, and can pose a serious threat to human health and to the environment. The inefficient handling of biomedical waste is more

DOI: 10.4018/978-1-7998-3479-3.ch091

likely to cause problems such as blood borne pathogens to the groups at highest risk, namely; healthcare staff, scavengers, and municipal workers (from needle sticks for example, if the biomedical wastes are handled and disposed together with domestic wastes). In many countries, cities are with inadequate segregation of hazardous and non-hazardous biomedical wastes, as well as a lack of suitable waste treatment facilities and methods. These cities also have either unregulated or non-existent legislation, with regard to waste processing and treatment, in addition to inefficient training of personnel and lack of personal protective measures (Askarian *et al.*, 2004; Marinkovic *et al.*, 2005; Rasheed *et al.*, 2005; Soliman and Ahmed, 2007).

Medical solid wastes management is an important factor in environmental hygiene and needs to be integrated with total environmental planning (Oke, 2008). Elements of waste management include characterisation, storage, collection, transportation, treatment and final disposal. Although, the World Health Organization (WHO, 2004), US Environmental Protection Agency (EPA, 1991), US Centres for Disease Control and Prevention, Italy (Liberti *et al.*, 1994, 1996), Finland, Japan and Germany (Miyazaki *et al.*, 2007; Miyazaki and Une, 2005; Tsakona *et al.*, 2007) have already established strict guidelines for the management of infectious waste materials, solid waste management is a major problem in most developing countries of the world due to its ever growing and endless generation coupled with poor management (Longe and Williams, 2006, Meghdad *et al.*, 2016).

BACKGROUND

In some countries, solid and medical wastes disposal is governed by laws of the Ministry of Environmental Affairs in collaboration with the Ministry of Health and Population. Regulations classify the waste from healthcare settings to be hazardous, and state that certain precautions should be considered during collection, handling and final disposal (Soliman and Ahmed, 2007, Meghdad *et al.*, 2016). One of the most important and initial steps in the development of a plan or in the performance of risk or cost analyses in the field of solid waste management involves a thorough understanding of the quantities and properties of the material that needs to be evaluated or treated (Diaz *et al.*, 2008). In this particular case, the material under consideration is healthcare waste. Unfortunately, there is a limited quantity of reliable information in the open literature on the quantities and characteristics of the various types of wastes that are generated in healthcare facilities (Diaz *et al.*, 2008). Furthermore, most of the reports dealing with analyses and evaluations conducted on the performance of a particular type of treatment method either in industrialized or in developing countries do not clearly specify or characterize the quality of the waste undergoing the treatment. Article provides basic information on the quantities, characteristics; collection, transportation and disposal of the solid wastes generated in various types of healthcare facilities located in industrialized and in developing countries are rare (Diaz *et al.*, 2008). This therefore calls for documentations on such important waste with a particular attention to prevention spreading of infectious diseases and to aid environmental engineer in the design of disposal facilities. The main objective of this study is to presents documentations on health care solid wastes with a particular attention to prevention spreading of infectious diseases and to aid environmental engineer in the design of disposal facilities.

Medical Wastes Treatment and Disposal Practices

Treatment of toxic and infectious waste has been defined as any method, technique or process designed to change the biological character or composition of waste to render it non-toxic or non-infectious. There

are several factors to consider when selecting among the medical waste treatment methods (Manyele *et al.*, 2003, PATH, 2005, Visvanathan, 2006, Paweł, 2019). In the selection of treatment process for medical waste the capital cost, the operating costs, the running cost of pollution control and waste preparation equipment, operating charges, sterilization efficacy, maintenance and higher operator skills, air emissions, water emissions and the characteristics of treated waste are factors that must be considered (Manyele *et al.*, 2003).

Waste Collection, Transportation, Storage and Segregation (sorting)

Collection and transportation of medical waste remains a serious concern in most of the countries in the world as improper collection and transportation endanger the environment.. Collect and store compatible wastes in strong, tight containers in a secured area (protected from the weather, such that none can escape by gravity into the environment. Keep lids tightly secured when not in use. Medical waste transportation refers to the haulage and handling of waste from inside healthcare facilities to treatment sites, which can either exist on-site at a hospital or be a central off-site facility. A second transportation phase typically occurs when the treated waste residual, typically ash from an incinerator or waste sterilized through autoclaving or microwaving, is moved to a landfill for final disposal

Segregation of waste in a hospital affects infection control, patient safety, occupational health (in the hospital), and overall community health and the environment. It also helps to cut down emissions of greenhouse gases, persistent organic pollutants (POPs), mercury and other hazardous waste. At hospitals and other healthcare facilities, waste is generally sorted into color-coded bins or bags, with each receptacle denoting a different waste stream or waste type. The colour selected for each waste type, along with what types of waste go into each stream, varies from region to region, with some using the source of the waste as a basis for sorting, while others use the likelihood of objects (pathogenicity to determine its disposal waste stream).

Medical wastes are stored in containers with colour code (Visvanathan, 2006, Paweł, 2019). Colour is used to differentiate hospital waste at the generation point. Infectious wastes are stored in a yellow marked, strong leak proof bag or container. Chemical and pharmaceutical wastes are stored in a brown marked plastic bag or container. Black marked plastic bags in containers are used for storing general waste. Radioactive wastes are stored in a red lead box labelled with a radioactive symbol. Sharps are stored in a yellow marked puncture proof container with covers on them. Infectious, pathological and chemical wastes are usually collected in red plastic bags (Nemathaga *et al.*, 2008). In Serbia segregated pharmaceutical waste is packed in the red containers or red bags, while cytostatic waste is packed in purple containers or bags. Infectious waste is packed in yellow bags or containers; and other hazardous waste (chemical) - in red containers. In the most EU countries there is the same colour coding system since Serbian model for colour coding of healthcare waste streams is taken from the EU countries experience and practices.

Medical Wastes Treatment Methods: Methods of infectious wastes treatment are well documented in literature, but its applications varied from countries. The general or common methods are incineration, burying (landfills) the wastes, open burning, autoclave, chemical treatment, hydropulping, and compaction.

- **Open Burning:** If infectious and medical wastes cannot be taken to an incinerator, they may be burned in a drum, protected hearth, or an open pit. Drum burning is preferred to open pit or open burnings because combustion is better and temperatures are higher. The advantages of burning in

an open drum are that its materials are available locally and it has a low cost. The disadvantages include the followings

- a. Requires supervision for proper usage.
- b. Does not burn as cleanly as a special incinerator .there may be smoke and environmental emission hazards.
- c. Fuel is required.
- d. Needles will not be destroyed, so residual metal and ash remain a hazard (though they are not infectious after burning).
- e. Hot, molten plastic is a serious hazard and burning pits may not work well in the wet season.

An open oil drum is among the best solution for burning. The drum, with top and base removed, are placed on a steel grid, which is raised off the ground with bricks to allow good air circulation. If a drum is not available, an open brick hearth can be used instead. Sweep molten plastic and ash into an ash pit behind the hearth. Finally, if neither burning in drum nor in concrete drum is feasible, burn waste in an open pit. Take care to ensure that all the infectious wastes are burned because shallow pit burning is not very efficient. Burning infectious and medical wastes in an open drum, protected hearth or pit is the next environmental friendly method to incineration. It should be noted that burning waste should be protected so that wind does not blow hot ash and so that molten plastic cannot burn people near the fire.

- **Burying and Land Fill:** If for some reasons infectious and medical wastes cannot be burned, the wastes can be buried in a pit or in an approved land fill site. Literature such as Askarian *et al.* (2004 a and b); Marinkovic *et al.* (2005 and 2008); Oke (2008); Rasheed *et al.* (2005); Daiz *et al.* (2005), Batiu *et al.* (2018) present facilities for burying infectious and medical wastes.

The advantages of burying infectious and medical wastes are:

- a. No additional equipment required and no smoke.
- b. No fuel and maintenance are needed.
- c. the capital, operational and maintenance costs are low.

The disadvantages of the treatment method are as follows:

- a. Digging deep pits and covering them places enormous burden on staff (is a lot of work)
- b. Syringes can be unearthed accidentally (or on purpose).
- c. Pits cannot be used when the water table is near the surface because liquids leak into ground water and infectious and medical wastes may surface over time.
- d. Hard ground may make digging difficult.
- e. infectious and medical wastes are bulky and some infectious and medical wastes may never degrade
- f. The environmental cost is high and much land is needed

This option should only be used when: no incinerator is available, burning is not acceptable or possible and suitable land is available (the land should be securely protected and not accessible to children and the community, the water table should be at least 1.50 m below the base of the pit, even during the wet season and the ground must not be too hard). Burying infectious and medical wastes in the ground is the least safe method because of its tendency to pollute ground and surface water. Since landfill operations may cause loss of containment integrity and dispersal of infectious waste, it is recommended that all infectious waste be treated prior to disposal. Open pit burning or burial of medical waste should be discouraged. To control and minimize the levels of environmental pollution and occupation health injuries from incineration processes, the hospital must control the

waste stream, for example, avoiding certain materials in the waste stream and sorting the wastes at the point and time of generation.

- **Incineration:** Incinerator in developing countries is self-made and is constructed from burned bricks and cement; it has a shape of house fireplace. Waste is burned using coal as fuel, which does not allow proper control of temperature. A high amount of ash is generated because of the incomplete burning of waste. Its chimney is also short and, depending on wind direction, emitted gases are dispersed to nearby communities, causing nuisance and being a potential cause of bronchitis and pulmonary ailments such as asthma (Mato and Kassenga, 1997 Mato *et al.*, 1994). Waste that is improperly incinerated, especially that containing plastic materials is known to give rise to toxic gases such as dioxins and furans that are carcinogenic (Lee *et al.*, 1996). Plastic materials as part of the waste encourage the release of dioxins when incinerating them. This is because plastics contain chlorine by-products such as polyvinyl chlorides (PVCs, Mato and Kassenga, 1997). The problems of medical waste treatment are typical of any developing country that cannot afford to buy more environmentally friendly incinerators with the latest technology (Nemathaga *et al.*, 2008). Visvanathan (2006) reported that incineration is the common methods in Asian countries. Figures 1 and 2 show typical incinerators fabricated using local materials in Nigeria. Incineration is a perfect method for all types of HCW, both hazardous and non-hazardous (Hasan and Rahman, 2018, Abu Mhady *et al.*, 2019).
- **Autoclaving:** The autoclaves have a temperature range of 50°C –250°C, but they are operated at 160°C as the optimum temperature to kill bacteria and infectious diseases, but not to melt any materials that are introduced. Autoclaving is now recognized as an important method for treating various kinds of infectious hospital waste. Its major drawback is that it cannot handle large quantities of hazardous waste. Sharps are generally known to be capable of transmitting diseases. Safe handling and disposal of sharps is an essential part of any infection control program (Nemathaga *et al.*, 2008). Autoclaving is suitable for sterilizing hazardous waste. However, the volume of waste cannot be reduced in this process. It is not suitable for recognized body parts (Hasan and Rahman, 2018). On the other hand, the hydropulping, an oxidation technique, has the required water content of approximately 80% as a result of an increase in weight; however, the resultant volume can be as little as 30% of the original volume. The use of a pulping system is highly controversial for clinical waste treatment. The compaction system can reduce the waste volume up to 60%. However, sterilization is not possible in this method. A thorough description of technology with their strengths and weaknesses, as well as some key factors for technology selection, has been presented in preceding publications (Hasan and Rahman, 2018).
- **Open dumping:** Open dumping has long been recognized as a potential source of public health and environmental problems. Generally landfill has accepted as the final option of resting hazardous hospital solid waste. Open dumping, because of its inherent problems such as leakage of toxic substances into the environment; easy access from insects, rodents and other small animals, most of which are disease vectors, has been replaced by landfilling in the management of solid wastes (Nemathaga *et al.*, 2008).
- **Landfill:** The main idea of the landfill is for storage and containment of the waste deposited into it. At present, the landfills are operated like an open dump in some countries. Each day, the general and medical wastes are dumped in the landfill and later burned. Burning is aimed at reducing the volume of waste and stopping the spread of papers. This process is repeated until the landfill is full, and then the landfill is covered with soil. In normal operation of the landfill, the wastes are spread over, compacted and then covered with a layer of soil on a daily basis. This eliminates the

need for burning the waste as practised some hospitals. The burning itself is a potential source of generating toxic chemicals. This is more likely since wastes such as plastics, syringes and paper are burned together. There is high chance that toxic chemicals like dioxins and furans are generated. The community living near the landfill therefore acts as passive samplers through inhalation of polluted air. The landfills at the hospitals are supposed to be divided into two portions, one for putting general waste and the other, medical waste. Only general waste is supposed to be burned. However, in practice this is not followed. Both general and medical wastes are mixed at the landfill and burned together (Nemathaga *et al.*, 2008).

- **Recycling:** Recycling of solid waste at some hospitals in developing countries is being undertaken at a small scale level. Most the waste that is being recycled is leftover food. Other general wastes that have potential for recycling but that are not recycled include plastic bags, plastic containers and cans. These plastics come from various sources within the hospital, but the major percentage comes from cafeteria related service (25%) and medical packaging (26%, Lee *et al.*, 2002). Most of the cans also come from cafeteria related services and within the hospitals; these were mainly empty cans of drinks or beverages used by patients, staff and visitors at the hospital. Plastics and cans have a high potential to be recycled (Nemathaga *et al.*, 2008).
- **Disinfection:** In order to reduce the toxicity of some medical wastes, chemical disinfectants (chlorine dioxide, sodium hypochlorite, or per acetic acid) are sometimes used. For solid wastes, disinfection is effective if only waste materials are shredded. In some cases, the disinfectants themselves are hazardous, thus it is not recommended for treating pharmaceutical, chemical and some types of infectious waste (Zarook, 2012).
- **Disinfection by Plasma:** In this process, low temperature plasma which is produced by the plasma generator using air as working fluid organizes a combustion process. The medical waste is constantly mixed, thus it maximizes the heat and mass exchange which saves any energy loss. The heat produced is used as an additional heat source in the process. This technology eliminates the formation and release of irregular forms of NO_x and high-toxic substances (dioxins) into the atmosphere. Another main advantage is that it has low consumption of energy compared to other mineralization (combustion) processes (Zarook, 2012).
- **Emerging Technology:** A new technology for management of hazardous medical waste that transforms the regulated medical waste into municipal solid waste is recently introduced. This method involves shredding and grinding the infectious medical waste bags via sharp cutting blades that are installed within the vessels. The blades rotate around 1750 revolutions per minute and the volume of the shredded waste is reduced by 80%. The steps included in the process are loading, shredding, heating, sterilization, cooling, draining, vacuum and unloading. The whole process is enclosed in a compact system and there is no intermediate handling of the waste within the process. Due to the compact size, this system can easily be used for on-site treatment of the waste and installed in hospitals. This will reduce the transportation costs of the medical wastes. In terms of environmental aspects, it is a clean and chemical-free technology and does not have any hazardous emission or radiation. This method is economical and environmentally friendly and is reliable in terms of ease of use and maintenance. This technology is currently practiced in the middle-eastern countries such as Iraq, Jordan, Kuwait, Lebanon, Syria and United Arab Emirate (Zarook, 2012).

Medical Wastes Management Techniques

Improved health-care waste management requires awareness raising; a legal framework and a policy, which have to be implemented locally; waste management plans for health-care establishments; staff training. The elements of a well-documented infectious waste management plan can be outlined as designation and identification, segregation, packaging, storage, transport and handling, treatment techniques, disposal of treated waste, contingency planning and continued staff training (Manyele, 2004; Visvanathan (2006), Blackman, 1996; Griffin, 1989). The step by step waste management techniques are generation, segregation (sorting) storage, transportation, treatment and final disposal.

- Waste generation in both developed and developing Nations:** Bakiu and Durmishaj (2018) reported that highly developed countries have a larger production of medical waste than middle developed and developing countries. Highly developed countries produce 1.1–1.2 kg per capita, 0.4–0.5 kg of which is hazardous waste; middle developed countries produce 0.8–6 kg per capita, 0.3–0.4 of which is hazardous waste; and developing countries produce 0.5–3 kg of waste per capita. In Croatia annual waste production per capita is 1.2 kg, out of which 0.16 kg is hazardous medical waste. Comparison of world data shows large differences in daily medical waste production between affluent and poor regions. North America produces 7–10 kg of waste per hospital bed daily, Western Europe 3–6 kg, whereas South America produces 3 kg, and Eastern Europe 1.4–2 kg per bed. The difference in quantities results from the fact that developed countries invest much more money in health systems, leading to larger amounts of medical waste generation. Meghdad *et al.*, (2016) stated that medical waste production rate per active beds in selected hospitals in Iran were comparatively less than Tehran-based (2.71 kg/day.bed) and Zanjan-based (2.402 kg/day. bed) hospitals. Visvanathan (2006) reported that medical waste generation in some countries as 0.8–1.67 kg/bed/day in Bangladesh, 0.27 kg/bed/day in Bhutan, 1.0–2.0 kg/bed/day in India, 1.90 kg/bed/day in Malaysia, 0.5 kg/bed/day in Nepal, 1.06 kg/bed/day in Pakistan, 0.36 kg/bed/day in Sri Lanka, 0.68 kg/bed/day in Thailand and 2.27 kg/bed/day in Vietnam. Paweł (2019) stated that medical waste generation in European's countries as 1.22, 1.76, 0.13, 0.63, 0.40, 1.39, 1.23, 0.23, 1.64, 4.80, 0.06, 0.01, 1.46, 5.03, 2.40, 0.20, 0.19, 5.07, 0.57, 0.57, 0.76, 3.79, 0.32, 4.12, 2.68, 2.40, 0.63 and 22.52 kg/bed/day in Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden and United Kingdom respectively. Hasan and Rahman (2018) stated that healthcare waste generation rate and hazardous healthcare waste generation rate in Khulna city, Bangladesh were 0.90 kg bed⁻¹ day⁻¹ and 0.18 kg bed⁻¹ day⁻¹, respectively. Abu Mhady *et al.* (2019) documented that medical waste in Greece was varied from 0.00124 kg/bed/day (private psychiatric hospitals) to 0.718 kg/bed/day (public university hospitals), whereas in Bangladesh, the rate was 0.57 kg/patient/day. The rate of medical waste in Palestine was between 0.33 and 0.84 kg/patient/day, but updated report found 1.306 kg/bed/day and an occupancy rate of 80% other reports found 0.85 kg/bed/day. Nevertheless, the generated waste in Iran included 51.6% of infectious waste, 47.2% general waste and 1.2% sharps. Minas *et al.* (2017) presented medical waste generation from all the regions as follows:

- In Africa medical waste generation (kg/ bed/ day) for Algeria (0.96), Cameroon (0.55), Egypt (1.03), Ethiopia (1.1), Mauritius (0.44), Morocco (0.53), Sudan (0.87), Nigeria (1.68) and Tanzania (0.75);

- b. In Asia medical waste generation (kg/ bed/ day) for Bangladesh (1.24), Malaysia (1.9), China (4.03), Pakistan (2.07), India (1.55), Indonesia (0.17), Palestine (2.02), Indonesia (0.75), Thailand (2.05), Iran (3.04), Turkey (4.55), Japan (2.15), Nepal (0.5), Jordan (2.69), Lebanon (5.7), Korea (2.4), Kazakhstan (5.34), Laos (0.51) and Vietnam (1.57);
 - c. In America medical waste generation (kg/ bed/ day) for Argentina (3.0), Ecuador (2.09), Brazil (2.94), El Salvador (1.85), Canada (8.2) and USA (8.4); and
 - d. In Europe medical waste generation (kg/ bed/ day) for Bulgaria (2.0), Netherlands (1.7), Italy (4.0), Norway (3.9), France (3.3), Spain (4.4), Germany (3.6), Latvia (1.18), Greece (3.6) and UK (3.3).
- **Composition of medical wastes:** One important component of a waste characterization program involves the determination of the composition of the wastes. A sound understanding of the contents of the waste stream, in particular the contents of the non-infectious fraction of the waste is helpful in the development of realistic waste reduction and recycling programs. The composition of hospital wastes generated in institutions in Peru shows that a substantial amount of the wastes consists of paper products, plastic and textiles in the form of cotton and gauze. This medical solid waste generation depends on several factors such as institutions mode of operation, unit, number of patient, number of beds and rooms, habit and culture of the patient and climatic conditions.
 - **Bulk density of medical wastes:** Bulk density is defined as the uncompacted mass of a material occupying a known volume. Bulk density generally is reported as mass per unit of volume (kg/m^3). In waste management, it is important to know the bulk density of the waste or components of the waste for a number of purposes, which include: determination of storage space, definition of size for the collection vehicle and estimation of the requirements for processing equipment (compaction, size reduction, disinfection and others). Diaz *et al.* (2008) shows that the bulk density for the entire waste stream ranged from 137 to 359 kg/m^3 , with an average of 218 kg/m^3 in Peru. The average bulk density for common (general) waste was 211 kg/m^3 , that for contaminated waste was 226 kg/m^3 and that for special waste was 139 kg/m^3 . The bulk densities of various components of healthcare wastes generated in Guayaquil, Ecuador show that the densities vary from about 56 to 960 kg/m^3 (Diaz *et al.*, 2008). The data provide the results of thermo-chemical analyses, including heating value, for several components of the waste. Other physical-chemical characteristics for hospital wastes generated in Saõ Paulo, Brazil, (by type of generator) are in the range of 56.22 to 959.71 kg/m^3 with an overall average of 261 kg/m^3 . These variations in the bulk densities can be attributed to various factors as institutions mode of operation, unit, number of patient, number of beds and rooms, habit and culture of the patient and climatic conditions. These results indicate that waste reduction techniques may not be applicable in some places.
 - **Segregation of medical wastes:** Segregation is useful since it prevents the contamination of non-hazardous waste by the hazardous waste and making the whole waste stream hazardous. The method reduces the toxicity and the volume of the waste stream. Segregation makes it easier to transport the waste. Waste is segregated depending on the quantity, composition, and the disposal method of the waste stream (Zarook, 2012). Immediately after used, infectious and medical wastes should be discarded in an appropriately colored container with a plastic liner bag. If infectious and medical wastes are to be disinfected and sent for recycling, they should not be mixed with non-infectious wastes. Despite the commendable level of segregation of immunization and medical wastes currently achieved in medical waste management practices, literature revealed that in developing countries segregated immunization wastes are sometimes mixed together by collectors at the collection points or at the dump sites on the basis of lack of provision for separate transpor-

tation or disposal sites. This indicates that the whole mixed waste could be considered as being infectious waste, which portends a serious risk to the general public and the environment (WHO, 2004; Longe and Williams, 2006)

- **Shredding of medical wastes:** infectious and medical wastes may be shredded in a hand mill or an electric shredder so as to reduce their volume. After shredding they may be buried on-site.
- **Encapsulation of medical wastes:** Encapsulation means surrounding dangerous materials with a substance that will harden. Encapsulation ensures that infectious and medical wastes are stuck in a material, so that used materials (infectious wastes) cannot be harmful or reused. Filled infectious and medical wastes containers are placed in a metal drum or a high-density plastic container up to 75% of the final capacity. An immobilizing material such as fresh cement, bituminous sand or clay is added in the container. Once dry, the container is sealed and disposed of in a land fill or buried on site.
- **Storage of medical wastes:** Infectious Waste, wherever it arises, should be disposed of as soon as it is practicable to do, so arrangements for disposal, and for storage pending disposal. Storage will differ depending upon where the waste is generated, on the nature and quantity of the waste and perhaps on geographical and/or weather constraints. In all instances, storage arrangements should:
 - a. allow safe handling of Infectious waste packaging;
 - b. allow clear distinctions to be maintained between infectious wastes intended for different disposal methods, or, in the case of storage in patients' homes, between infectious and domestic wastes, as the means of disposal are different;
 - c. allow for storage of Infectious wastes without offensive odour;
 - d. be of sufficient size to allow for delays in the onward transportation of the waste.

The local circumstances, the nature and volume of the infectious waste to be stored should be taken into account when determining storage conditions. Where necessary, advice on storage conditions should be sought from the relevant Health and Safety Adviser or Infection Control Adviser.

- **Transport of medical wastes:** Arrangements for the collection and transport of infectious waste should be:
 - a) compatible with the arrangements made for storage of the Infectious waste;
 - b) made, in the context of the Waste and Contaminated Land (FEPA, 1991) to permit ready delivery to the means of treatment or disposal which has been arranged;
 - c) be compatible (particularly in the case of Infectious Waste created in patients' homes) with the reasonable expectations of patients, health and social care and waste management personnel in relation, for example, to working practices; and
 - d) complied with health and safety and environmental legislation and good practice, especially regarding the health and safety of patients, carers, health and social care staff, waste management personnel and others.

In both developed and developing countries, all the wards have individual safety boxes, and other wastes generated had a general box of either polyethylene or other plastic. These can be regarded as internal storage facilities for waste collection and storage. In developing countries of the world, collection of immunization waste from the wards to the stations (immunization offices) is effected immediately after the EPI activities, and the frequency of collection from the immunization offices by external

waste collectors is irregular (collection could be 2 or 3 weeks after the program). In some developing countries, transportation from wards to the immunization offices is either by car, lorry, motor-bicycle or other method depending on distance and logistics. Transportation to the disposal sites is by the same methods, which are found to be irregular and not adequate.

- A. **Current Medical Waste Treatment and Disposal Practices in Developed Nations:** At hospitals and other healthcare facilities in developed nations, waste is generally sorted into colour-coded bins or bags, with each receptacle denoting a different waste stream or waste type. The colour selected for each waste type, along with what types of waste go into each stream, varies from region to region, with some using the source of the waste as a basis for sorting, while others use the likelihood of an object's pathogenicity to determine its disposal waste stream (Bakiu and Durmishaj, 2018). This lack of standardization makes effective waste sorting difficult for healthcare workers, and causes workers to err on the side of caution, disposing objects in the infectious waste stream and causing unnecessary infectious waste generation (Bakiu and Durmishaj, 2018). Another issue with medical waste disposal is ensuring that persons do not come into contact, whether accidentally or on purpose, with disposed-of infectious items. In most jurisdictions, healthcare facilities have a legal responsibility to ensure that patrons and staff do not come into contact with infectious waste once it has been placed in a disposal bin (Bakiu and Durmishaj, 2018). Studies, focused mainly on the UK, have found that hospitals do not have adequate safeguards to prevent these contacts with hazardous medical waste, and that safe-handling procedures are frequently neglected (Bakiu and Durmishaj, 2018). This inadequacy is both a source of infection and a legal liability for hospitals, should patients become ill from poor waste management practices. Further reinforcing the need for adequate safeguards in healthcare facilities, the EPA has concluded that the disease-causing potential of medical waste is greatest at the point of generation and naturally tapers off after that point. Thus, safeguarding of infectious medical waste within healthcare facilities ought to be made a top waste management priority.

Medical waste transportation refers to the haulage and handling of waste from inside healthcare facilities to treatment sites, which can either exist on-site at a hospital or be a central off-site facility. A second transportation phase typically occurs when the treated waste residual, typically ash from an incinerator or waste sterilized through autoclaving or microwaving, is moved to a landfill for final disposal (Bakiu and Durmishaj, 2018). It is common practice for healthcare facilities to have their infectious waste stream transported by a third-party firm, contracted to take the waste from the healthcare facility to an appropriate waste depot (Bakiu and Durmishaj, 2018). These firms typically collect the waste from a few central points in a healthcare facility and then transport the waste to a disposal facility that is able to safely handle medical waste. However, there are issues with the process of contracting out waste disposal. The use of third party disposal firms poses a challenge from an incentives point of view, as the waste disposal firms, or the individuals who work for them, can pocket large sums by improperly disposing of the waste.

Disposal fees for medical waste in developed countries are very high, with hospitals in the UK frequently paying in excess of £450 per tonne for contractors to dispose of their medical waste and hospitals in the United States typically paying \$790 per tonne for medical waste disposal (Bakiu and Durmishaj, 2018). These high prices create an incentive for third-party medical waste haulage firms to dispose of the medical waste without treatment in unregulated and less expensive ways, rather than transport the waste to a proper treatment facility for sterilization. In Ireland, waste truck operators can pocket over \$2000 by illegally dumping a truck full of medical waste rather than tak-

ing it to a regulated disposal site, thus creating a very strong incentive for illegal dumping (Bakiu and Durmishaj, 2018). Developed nations increasingly have to grapple with the problem of illegal medical waste dumping, which can be particularly chronic if the country has a weak infectious medical waste tracking system. Illegal dumping is a significant issue, as these untreated infectious waste deposits present a health risk to the public due to potential for pathogen release, and a drain public fund as cleanup costs for medical wastes are extremely high (Bakiu and Durmishaj, 2018). Another problem relating to illegally disposing of infectious medical waste occurs in developing countries such as India, where governments are grappling with disease outbreaks due to third-party firms receiving medical waste from healthcare facilities and then reselling items such as sharps on the black market for re-use (Bakiu and Durmishaj, 2018).

Zarook (2012) stated that a new patented technology that helps in better management and treatment (new technology for management) of the medical wastes had been developed America. Based on this technology, Med-Shred, Inc., (Texas, USA) has developed a mobile shredding and chemical disinfecting machine that is aimed for on-site treatment of hazardous medical waste (Zarook, 2012). The machine converts the medical waste into disposable municipal waste using shredders that shred the waste into smaller particles which are then wetted with disinfectant spray and immersed in a disinfection solution. The wet waste is then dried using a hot off-gas in a drying chamber. Considering the number of clinics and hospitals in, middle-east, this method will be very successful if utilized, as it can treat the medical waste on-site which helps in better management of wastes.

- B. Current Medical Waste Treatment and Disposal in Developing Nations:** In developing nations, there are two key hospitals (public and private). Public hospitals represent 47.6%, while private and philanthropic hospitals represent 28.6% and 23.8%, respectively (Da Silva *et al.*, 2005). Manye *et al.*, (2003) revealed that in developing nations, incineration, open burning and burial of immunization waste (both infectious and non-infectious wastes) were practiced. A common practice is the disposal of infectious and regulated waste either in shallow pits (cemented or earthed) within the immunization office premises or in a locally developed incinerator. These observed immunization waste management practices are a risk to public health, especially when densely populated communities surround immunization offices. Studies revealed that collaborative efforts do exist between the immunization and health officers and the local government waste disposal board. Immunization and medical wastes are collected from the offices by the board and disposed of at government approved dumpsites or landfill sites. The only setback from this collaboration is that waste collected by this board is mixed with non-infectious waste and dumped at the site. The implication of this practice is that all of the wastes are now contaminated and could be classified as infectious waste. Other notable major problems in all of the surveyed sites were open dumping, burial or burning either within the immunization offices or at government recognised dumpsites, and non-treatment of infectious waste before final disposal.

Literature revealed that elsewhere, burning and burial of medical waste are practiced. Sadly enough medical infectious waste is not excluded from this practice. A common practice is the disposal of infectious and regulated waste types either on fallow land within hospital premises or in canal. This observed poor medical waste management practices is a risk to public health especially when most hospitals are surrounded by densely populated communities. In some countries in developing nations public hospitals are equipped with incinerators, which only being functional at the early years. In public hospitals with incinerators, infectious medical waste and sharps are incinerated in-house by the hospital's engineering department and engage the service of an environmental officer to oversee the treatment and eventual disposal of its medical waste.

In some developing nations, a collaborative effort does exist between public hospitals with facilities and some private hospitals for the incineration of their infectious and sharp waste types. This collaboration is guaranteed the quality of the environment. Some hospitals employ the services of private waste collectors for medical waste collection and final disposal at government authorized dumps. Notable among these private collectors is the state owned waste management authority that specializes in the collection of industrial wastes from most industrial set ups within the mega city. The major observed challenges to the environment are open dumping either within the hospital premises or at government recognized dumpsites; and non treatment of infectious waste before final disposal. Open dumps are known to have no controls over access of unauthorized persons or environmental pollution, hence, the potential health risk (WHO, 1999). Although, national policy on environment stipulates specific roles for appropriate government agencies to be among others; the determination and the use of environmentally safe and technologically sound techniques for disposal of toxic, hazardous and radio-active wastes in developing nations. Literature describes that various dumpsites within the vicinity of the metropolis do not meet necessary design criteria to operate as landfills for hazardous waste.

Medical waste even though, attracted a high level of segregation in most hospitals in developing nations. It is generally co-disposed with the municipal solid waste stream by waste handlers. The disposal of medical waste in municipal landfills therefore poses serious health and environmental hazards erstwhile landfills are mostly open dumps without adequate design consideration to guaranty protection of the environment from the disposal of such hazardous wastes. Treatment of infectious waste and sharps waste needs adequate legal backing and sanction in case of non-compliance by erring hospitals, health institutions and clinics. Leachates from beneath the landfill base may contain heavy metals and other organic pollutants that could lead to gross contamination of surface and groundwater resources (Longe and Williams, 2006).

Hazardous medical waste requires proper monitoring for an effective tracking at all times. Control of medical waste can only be fully achieved when adequate monitoring facilities are available. Control means that competent authorities can act rapidly to ensure the possibilities of minimizing inappropriate handling and dumping of medical waste. It also translates to mean that regulatory authorities should have the powers both legally and financially, to act quickly in order to reduce dangers posed to human health and the environment. In order to enhance adequate monitoring and control of medical waste in developing nations, governments at national and state levels need a comprehensive guideline on hazardous solid waste management other than what is currently in existence. For effective management therefore, there is need for cooperation among medical waste generators and environmental agencies with coordination among the various persons and corporate bodies involved in the control of medical waste activities. Also, handlers of medical waste within health care facilities should be trained on methods and new techniques of medical waste management and in hazardous effects of medical waste using WHO manual (WHO, 2005b; MINTER, 1979, CONAMA, 1993; COSEMA, 2000)

FUTURE RESEARCH DIRECTIONS

Research directions should include factors that can significantly improvements the current practices of handling and management of health care wastes in developing countries are required in order to ensure public health and environmental protection as well diverting significant quantities of material and resources from landfill.

CONCLUSION

It can be concluded that the:

- Medical waste generation varies from 0.17 to 8.4 kg/bed/day,
- Bulk density of the entire waste stream ranged from 137 to 359 kg/m³, with an average of 218 kg/m³,
- average bulk density for common (general) waste was 211 kg/m³, that for contaminated waste was 226 kg/m³ and that for special waste was 139 kg/m³,
- infectious (clinical, yellow bag) waste generation varied from 0.38 to 3.50 kg/bed-day;
- hospital waste generation (both infectious and mixed solid waste fractions) varies from 0.35 to 3.50 kg/ bed-day, and
- medical waste management practices varies from poor in developing nations to fair in developed nations

ACKNOWLEDGMENT

The authors wish to acknowledge the following people FEYIJIMI, O.O (CVE/2001/039);HASSAN, O.A (CVE/2001/040); OGinni, E.O (CVE/2001/053); OKAFOR, I.A. (CVE/2001/062); OLADELE, A.O. KEY TERMS AND DEFINITIONS

BHW: Biohazardous wastes.

EPI: Expanded Program on Immunization. The Expanded Program on Immunization is a World Health Organization program with the goal to make vaccines available to all children

IV: An intravenous central line is a kind of intravenous (IV) line used to give medicines and fluids. It is a thin, soft, plastic tube called a catheter that is inserted through the skin and into a vein.

MW: Medical waste.

MWC: Medical waste commission.

MWM: Medical waste management.

MWMP: Medical waste management plan.

RCW: Recyclable wastes.

SW: Sharp wastes.

TP: Training program.

WHO: World Health Organization.

Managing Water Resources: Industry Initiative

10

Sabyasachi Nayak

Confederation of Indian Industry, India

INTRODUCTION

Water is inextricably linked to every aspect of life and development. The burgeoning population leading to spike in anthropogenic activity and climate change has put enormous strain on the fragile water resources. Continuing with the current water trajectory, country like India has witnessed a progressive decline in per capita availability. Numerous steps are initiated by the government to address the issue plaguing the water sector in India. But the involvement of various stakeholders is equally important.

The Indian industry has taken a proactive role in ensuring the proper management of the limited water resources by engaging with concerned stakeholders. This paper seeks to capture the grass roots interventions undertaken by industry in improving the management of water resources. As water can directly impact the livelihood therefore the conservation, revival and development of water resources calls for a comprehensive, holistic, scientific and sustainable approach. It puts into perspective the operational modality of industry in engaging with the community to manage water resources. The objective is to provide a dynamic insight into the operational model of the industry in addressing the accumulated neglect in the water sector. An assessment of the operating model reiterates the positive social, economic and environmental outcome in a sustainable manner. Therefore, it is proposed to explore operating beyond the level of “watershed” to larger level “river basin”. Going forward it is imperative to revive a culture of community base management of natural resources.

BACKGROUND

Water use has been increasing worldwide by about 1% per year since the 1980s. (United Nations Educational Scientific and Cultural Organization [UNESCO], 2019) Global water use has increased by a factor of six over the past hundred years. Levels of physical water stress are likely to increase as populations and their demands for water grow, and the effects of climate change intensify (UNESCO, 2018). The planet’s capacity to sustain the growing demands for freshwater is being challenged and by 2050, global water demand is projected to increase by 55% (UNESCO, 2017). Declining water resources are already affecting many parts of the world and an estimated 20% of the world’s aquifers being over-exploited (UNESCO, 2014). The gap between water supply and demand is projected to be of 40% in 2030. Asia will need on average 65% more freshwater withdrawals for their industry and energy sectors by 2030 in order for their national economies to grow as forecast (Water Resource Group, 2012). India is among the ten major water users in the world in terms of volume, which uses 646 km³ of water a year (UNESCO, 2009).

DOI: 10.4018/978-1-7998-3479-3.ch092

Water Resources: India

India's finite and fragile water resources are stressed and depleting, while sectorial demands (including drinking water, industry, agriculture, and others) are growing rapidly in line with urbanization, population increases, rising incomes and industrial growth (Government of India, 2001). The average rainfall is about 1170 mm which varies temporally and spatially (Government of India, 2015). About 80% of the country's surface water is polluted. The rivers Yamuna, Ganga, Gomati, Ghaghara, Chambal, Mahi and Vardha are amongst the most coliform-polluted water bodies in India. (WaterAid, 2015). India is the largest user of groundwater in the world with an annual extraction of 210 billion cubic meters. As per NASA study groundwater depletion in Rajasthan, Punjab, Haryana and Delhi was equivalent to a net loss of 109 cubic km from August 2002 to October 2008 (Government of India, 2010).

The irrigation sector consumes about 80% of the total water use which may reduce to about 70% by 2050, whereas the domestic sector and industrial consumption is projected to double during the same period (Government of India, 2014). India faces an unprecedented crisis in the next two decades. Today, major urban areas are unable to provide a reliable and regular water supply. Not surprisingly, aquifer depletion and inefficient water use are now endemic (UNESCO, 2012). The demands of a rapidly industrializing economy and urbanizing society come at a time when the potential for augmenting supply is limited, water tables are falling and water quality issues have increasingly come to the fore. It is no wonder then that conflicts across competing uses and users of water are growing by the day (Government of India, 2011).

Industry Water Initiative

In the advent of water crisis, the industries operating in the country will be the hard hit. Therefore the Indian industries collectively have taken a proactive role in ensuring the proper management of the limited water resources (Confederation of Indian Industry, 2006). The embracing challenge for industry is to play its appropriate role in effectively addressing unsustainable exploitation and contamination of freshwater resources (UNESCO, 2012). Industry has been showing ways of effectively managing the scarce water resource through proper engagement, networking and partnering with stakeholders (Confederation of Indian Industry, 2013). Industry is continuously seeking better ways to manage its water resources efficiently (Associated Cement Companies, 2013). Using a participatory development approach, construction and revival of water harvesting structures including Revival of village Ponds and Pasture land development is ensuring available water pre and post rainy season for drinking, cattle and irrigation purposes. Community is empowered to take local ownership of Water Projects and actively engages in creating solutions to water challenges .(Ambuja Cement Foundation, 2017).

Watershed Development Programme, designed to assist farmers in identified moisture-stressed has improved the water situation. The focus is not only seeking to achieve water conservation and soil enrichment, but also improving village-based management of water and other natural resources by evolving a culture of optimum water usage, finally leading to maximizing the benefits of water resources. (ITC Limited, 2017) Measures such as construction of check dams, ponds, excavation of streams, farm bunds for soil and water conservation practices enhances the availability and accessibility of natural resources on which rural livelihoods and economy depend (Lupin Human Welfare and Research Foundation, 2016). Rejuvenation of Rivers and Streams have proved extremely useful to convert rain fed farming into irrigated thereby improving the crop productivity. The intervention of Stream Revival mainly involves the excavation of the river beds and creating embankments to help channelize the water from the natural

Stream/ Rivers. The Check Dams are constructed across the river banks and Streams. This helped in increasing water storage in stream which was utilized latter for the irrigation purpose and it also helps augment ground water level in surrounding area (Kamalnayan Jamnalal Bajaj Foundation, 2017).

Water harvesting structures constructed serves as a critical source of irrigation for communities living in dry and rain-dependent areas. By implementing soil and water conservation practices communities have managed to substantially mitigate the impact of excessive rainfall as well as drought. [<https://www.reliancefoundation.org/water-security>] This has brought not only more cultivable area under irrigation but increase in cropping intensity from a single crop to double crops (Lupin Human Welfare and Research Foundation, 2017) . Similarly, sub-surface dykes and run-off diversion systems are able to provide water for irrigation for longer duration in a year, creating a positive impact on agriculture yields, as well as increasing accessibility of water for domestic use in water scarce areas. Salinity ingress in coastal areas is addressed through promotion of low-water intensive crops, renovation of ponds, and deepening of wells to recharge ground water resources (Ambuja Cement Foundation, 2015). In order to ensure effective use of water resources and raise awareness around water security issues, water budgeting is emphasized upon (Reliance Foundation, 2016). Training on modern agricultural practices to improve productivity includes drip irrigation, intercropping and vermicomposting (Asian Paints Limited, 2015).

FOCUS OF THE ARTICLE

The article focuses on the operational model of industry at grass roots level for managing water resources and a contemporaneous analytical assessment of the same. It examines how the industry beyond its “industrial operation” has partnered with community, developed requisite capacity of community and through robust monitoring & evaluation has brought about a desired change in the water scenario.

Operating Model

The model of operation resorted to by various industry for water management can be clubbed into two categories

- Direct implementation by industry through its Foundation/ Trust: Industry engages directly with the community through their trained and professional staff with the community.
- Implementation through NGO partner: Industry merely funds the initiative and the implementation responsibility is totally entrusted with the NGO

In both these models partnership with the community remains central and the intervention is projectivized – baseline Survey, assessment of Needs, proposed action, earmarking funds under each activity, time line, deliverables, mode of implementation, monitoring, documentation and exit strategy.

In the contemporary context forging partnership between Government, industry and community is critical to stimulate, strategize and synchronize the planning, development and management of water resources through a common integrated perspective. Such effort in a systematic and sustained manner has led to the evolution of multistakeholder partnership, incorporating a Public Private Community Partnership (PPCP) approach. The essence of PPCP in water related projects has been to pivot engagement between private sector and community in a synergetic operational mode to embark towards water security. The role of various stakeholders in multistakeholder PPCP is captured in table 1.

Currently, industry is implementing water related projects for the community adhering to the concept of watershed management which spans for five to six years. The overall management of watershed initiative is interdisciplinary with representation from hydro geologists, civil engineering, environmental science, hydrology, agronomist, veterinary and more importantly the social scientists. Harnessing the skills, expertise and competency of respective discipline in an integrated manner plays a pivotal role in influencing the outcome and impact of the initiative. The implementation of the project envisages a responsive governance mechanism, effective coordination between multiple partners, timely availability of funds and execution at the grass roots level to improve holistic water management. At the community level, Village committee embracing representation from community based organizations, youth, self-help groups, marginalized group galvanize the process of implementation in a participatory manner.

A robust monitoring & evaluation mechanism is put in place to provide improvement oriented direction, guidance and strategies in a participatory manner for introducing course correction measures and facilitate enhanced learning from ground realities. Participatory monitoring & evaluation conducted at the grass roots level assess progress, evaluate performance, and identify implementation issues. This has led to the evolution of a developmental process galvanizing action and results owned by the beneficiaries of the project. Monitoring & Evaluation is undertaken at various scale- day to day monitoring,

Table 1. Role of Stakeholders in PPCP

Role	Public	Private		Community	
	Government	Industry	NGO	Village Committee	Farmer
Capital Funding of the Project		√			
Technical expertise	√	√			
Community Mobilization		√	√	√	
Sensitization of Stakeholders					
Preparation of technical details					
Site Selection for construction	√		√	√	
Community interface			√	√	
Define Project Deliverables			√	√	√
Grass roots implementation			√	√	
Adherence to technical details	√	√	√		
Monitoring	√		√	√	
Capacity building on water use efficiency			√		
Operation & Maintenance of structures created				√	√
Demonstration of Water smart Agricultural Practices		√	√		√
Improved Water use efficiency			√		√
Crop diversification			√		√
Artificial recharge of wells			√	√	
Monitoring of wells			√	√	√
Water treatment			√	√	
Equitable distribution of water				√	√
Dispute Resolution				√	

periodic monitoring, concurrent progress monitoring, process monitoring and result monitoring. The overall Monitoring & Evaluation framework tracks the inputs, outputs, outcomes and impacts, thereby strengthening the data systems for better collection, collation, and analysis for tracking progress. A user friendly MIS system facilitates receiving systematic inputs from partner's to track progress- physical, financial, output and outcomes. Thus it helps stakeholders in availability of real time credible and reliable data to arrive at strategic decision to refine further plan of action and uphold transparency in operation by reinforcing accountability.

Requisite capacity development exercises taking into account the existing capacity and addressing areas to achieve desired capacity with the involvement of stakeholders and particular focus on community has led to improvement in functioning of activities at grass roots level. This quantitative and qualitative enhancement of human resources in applying their acquired skills, competency and knowledge has been instrumental in affecting the efficacy of the institutions at the grass roots level in undertaking planning, implementation, supervision and monitoring of initiative to improve water scenario. Technical competency focuses on implementation of integrated water resources management, improved agricultural practices, water budgeting, enhancing water use efficiency and water quality protection.

A responsive feedback mechanism at the grass roots in addressing the issues of the community has been vital in ensuring their active participation. The newly created extension service and field staff act as an interface between community and industry. In few project area users friendly WhatsApp has made a marked difference in terms of availing timely information, posting of pictures or sharing voice recording thereby establishing connectivity amongst stakeholders.

Assessment of the Operating Model

Collaborative, result oriented and focused partnership is the distinctive feature that has demonstrated in reaching out to varied stakeholders in harnessing their comparative advantages. Over the years, these models have been refined to reach the current form, which can be emulated by other industry while venturing into similar venture. The learning's emanating is essential in reinforcing efficacy of the intervention and evolving benchmarks for the implementation of projects at the ground level. In spite of the efficacy of the model a deep sense of skepticism pervades among other stakeholders, particularly the farming community whenever industry embarks on managing water resources. Therefore, gaining the confidence of the community and other stakeholder is a daunting task for the industry.

Industry has demonstrated its proactive role and earnestness to represent the need to seriously address the burning issue of water. Improving the water management has also ensured "ecosystem security". In overall terms, the positive social, economic and environmental outcome of the initiative has ensured a win situation for the varied categories of stakeholders. Transformation in the water sector is attributed to the creation of trained manpower, mobilization of resource and bringing about a mental revolution in management of the depleting scarce resource. In spite of this, funding has remained the fulcrum of partnership with industry thereby downplaying their managerial abilities, knowledge and expertise.

The essence of community ownership in terms of instituting, implementing and being accountable for the initiative is gaining momentum. This ecosystem has ripple effects on various aspects impacting the quality of lives of the community. With water as the central plank to development, the other areas where positive impact witnessed are reflected in table 2. The model re-cast the debate on water management in the contemporary context leading to development. There has been a positive shift from "dependency" to "development" which is realized by ensuring continuous, sustained and systematic engagement with the community.

Table 2. Outcome of Water Intervention

Social	Environmental	Economic
-Expand enrollment of girl child -Women participation in decision making -Curtailement in Household Migration -Reduced drudgery of women -Debt free farmers -Functional Community Organization	-Strengthen management of natural resources -Protection of ecosystem -Improvement in flora and fauna -Recharge of Ground water -Creation of water storage -Conjunctive use of surface and ground water -Improvement in water quality	-Increase in production and income -Diverse economic activity -Employment Opportunities created -Reduction in farm input cost -Slash in treating water borne disease

SOLUTIONS AND RECOMMENDATIONS

A serious multistakeholder partnership operating beyond the level of “watershed” to larger level “river basin” can make an impact in addressing the pressing issue of water management. **Figure 1** emphasizes 3D approach-“*Demonstrate Document Disseminate*” to venturing into “river basin” for implementation of water initiatives. The initiative should be cognizant to demonstrate that the planning, development and management of the scarce, fragile and finite water resources is undertaken in a unified manner without neglecting the “unity & integrity of the hydrological cycle”. It is equally important to documents the entire process for gaining an insight into the nuance and dynamics relating to various aspects of the project implementation. Furthermore, the documentation should be widely disseminate so that other stakeholder venturing into similar endeavor adopt the recommended approach and in the process need not reinvent the wheel.

As the water crisis looms across large parts of the country, therefore an amalgamation of scientifically rigorous orientation, participatory community approach, application of cost effective technology, demand management strategies, reinforcing improve water usage efficiency and resilience building can bring about a paradigm shift in water management. Nonetheless, bringing about behavioral changes will be instrumental in ensuring that the various activities undertaken are in consonance with the hydrological cycle. There is an urgent need for institutionalizing partnership between Government and industry, whereby desired impact can also be achieved in Government water management programs. Industry can also play a pivotal role identifying gap that deters the accrument of desired impact of government program.

Figure 1. 3D approach-demonstrate document disseminate

FUTURE RESEARCH DIRECTIONS

Community has the requisite wisdom but it needs to be harnessed in a scientific manner for bringing about the desired change. Active community participation, ownership and accountability are central to the success of water intervention. Therefore, future research may include a more thorough exploration of reviving effective community base natural resource management. It is imperative for the community to be the custodian, guardian and pride themselves on being steward of the natural resources. A mechanism making grass roots institution functional with requisite capacity and transparent operation can help in reinventing their water trajectory for the future.

CONCLUSION

Water management can be ensured through active participation and involvement of all stakeholders. In this direction industry has taken a proactive role by emphasizing the centrality of community participation. The prevalent operating model of the industry can be categorized into two parts -direct implementation by industry through its Foundation/ Trust; and implementation through NGO partner, focusing on- partnerships with community; robust monitoring & evaluation mechanism; requisite capacity development; and a sensitive feedback mechanism. With water as the central plank for development the ripple effects have been witnessed in other areas- agriculture, livelihood, education, health, poverty and empowerment. Thus, the operating model has been able to displace the entrenched “dependency” syndrome with “development”.

It is time to reckon multistakeholder partnership operating beyond the level of “watershed” to larger level “river basin” for making an impact in addressing the pressing issue of water management. Adhering to the 3D principle-“*Demonstrate Document Disseminate*” industry can contribute in creating the desired impact in other project settings. Simultaneously, research endeavor aimed at resuscitation and reassertion of community as the custodian of natural resource will be crucial. Going forward it is imperative to take a multidisciplinary stratagem, adopt participatory approach, and continuously strive for innovation and ingenuity thereby prioritizing local specific and customized solutions.

KEY TERMS AND DEFINITIONS

Hydrological Cycle: The origin, movement, and distribution of water in the planet.

Innovation: The process of evolving a new idea or concept from an existing practice bringing about a transformation in addressing a pressing issue.

Operating Model: The systematized approach adhered to by industry in ensuring delivery of requisite development outcome leading to improvement in the quality of lives.

Public Private Community Partnership: This deals with engagement of government, private sector, and civil society to achieve the aims of policy and ensure policy implementation.

Stakeholder: Stakeholders include individuals, groups, and institutions with an interest or concern in an endeavor.

Sustainability: Utilize, maintain, and conserve ecological balance by avoiding depletion of natural resources (in this case water) so that the demands of the present generation are met, simultaneously ensure that the concern of the future generation is not compromised.

Water Management: The process of planning, developing, and managing water resources in a holistic manner without compromising the needs of the future generations.

Water Security: Ensuring the availability and accessibility of reliable, safe, and sufficient amount of water in a sustainable manner.

Inhibited Antibiotic-Resistant and Electrochemical Treatment of Pharmaceutical Wastewater

INTRODUCTION

Water is vital both as a solvent in which many of the body's solutes dissolve and as an essential part of many metabolic processes within the human body. Potable water production and supply are essential ingredients in the community and to human beings and other living things. Waterborne diseases (diarrhoea, typhoid, and cholera) that are widely spread in developing countries and in sub-Saharan Africa are caused mainly by poor sanitation and hygiene practices, which involve collection, treatment and disposal of solid and liquid wastes. In wastewaters (liquid wastes) microorganisms are removed by disinfection treatment processes using Chlorine dioxide, Chlorine compounds (monochloroamine, dichloroamine), Ozone and ultra-violet radiations. The stringent potable water standard and effluents quality limits by Environmental Regulatory Authorities, increasing energy cost and reports of outbreak of water-borne diseases in many parts of Africa have brought a greater challenge to Water experts (Water Science, Environmental and Water Engineers). These actions have caused Environmental and Water Engineers to look for effective methods of treating water and wastewaters rather than relying on conventional water and wastewater treatment methods.

In the last two decades several studies have been conducted on the performance of electrochemical treatment process as a wastewater treatment method. The electrochemical treatment process has been effectively used in the treatment of various industrial, municipal, domestic- institutional and domestic wastewaters. Wastewater generated from industrial processes such as distillery industry (Manisankar *et al.*, 2004), textile industries (Naumczyk *et al.*, 1996) and dye processing industry had been treatment using electrochemical treatment process. Chen (2004) presented documents on the design development,

DOI: 10.4018/978-1-7998-3479-3.ch093

construction and applications of electrochemical techniques in water and wastewater treatment. In the documentation a particular focus was given to selected techniques such as electrodeposition, electrocoagulation, electroflotation and electrooxidation with little data on treatment of wastewaters from pharmaceutical industries. Over 300 related publications were reviewed with 221 cited or analysed. Literature (Li *et al.*, 2014, Zheng *et al.*, 2015) have provided more information on efficacies of various electrochemical treatment of water and wastewaters. The main focus of this study is to conduct a simple literature review on treatment wastewaters from pharmaceutical and related industries and establish efficacies of electrochemical treatment technique in removing selected pollutants form raw water.

BACKGROUND

Carbon resin electrodes were developed from used dry cells (Oke *et al.*, 2007a, b and c). Electrolysing equipment was developed from local materials. Synthetic (simulated) wastewaters were prepared using procedures and methods specified in APHA (1998). Fractional factorial (2^{K-P-1}) experiments were utilized at random to determine influence of selected factors (separation distance between the electrodes, volume of the wastewater used, applied current, temperature of the wastewater, treatment time, concentration of the pollutant, concentration calcium of hypochrite ($\text{Ca}(\text{OCl})_2$) added and depth of the electrode into the wastewater used) on efficiency of electrochemical process in removing Biochemical Oxygen Demand concentration at five days (BOD_5) as follow-up on previous study (Oke *et al.*, 2007c). The choice of the parameters to be studied was done on the basis of the theoretical data about several factors that determine the efficiency of an electrochemical method and the scarce knowledge concerning carbon-resin / aluminium electrodes. An electrochemical treatment plant on a laboratory scale using public electricity source was setup (Figures 1a and b). BOD_5 determinations in wastewaters were carried out following procedures in APHA (1998) using respirometric method (CAMLAB HACH, model number 2173B BOD manufactured by Hach Chemical Company). The procedures and steps were repeated for blanks (to serve as controls). Efficacies of the system were computed using equation (1) as follows:

$$Y = 100 \left(\frac{(C_0 - C_t)}{C_0} \right) \quad (1)$$

Where; Y is the efficacy of the system (electrochemical treatment process), C_0 is the initial BOD_5 and C_t is the final BOD_5 . Table 1 presents arrangement of Fractional factorial (2^{K-P-1}) experiments. Effects of the selected factors on the efficacy of the electrochemical treatment process were computed using contrast method (Guttman *et al.*, 1971; Gardiner and Gettinby, 1998; Davore and Farnum, 1999, Davore, 2000) as stated in equation (2) as follows:

$$ef = \left(\sum_{i=1}^{K-P-1} l_i Y_i \right) \quad (2)$$

Where; K is the number of the factors (8), P is the fraction of the factorial experiment (3), l_i is the level (-1 or 1), and ef is the effect of the factor. Number of experiments required for both factorial and fractional factorial were computed using the following equations:

$$N_{ffn} = 2^{K-P-1} \quad (3)$$

Where, N_{ffn} is the number of experiments required for fractional factorial experiments. Statistical evaluations were conducted using the following equations as follows:

$$SSQ = ef^2 \times (2^{K-P-2}) \quad (4)$$

Where; SSQ is the sum of square of the factor

$$MSS = \left(\frac{SSQ}{df} \right) \quad (5)$$

$$SST = \sum_{i=1}^N Y_i^2 - \left(\frac{\left(\sum_{i=1}^N Y_i \right)^2}{N} \right) \quad (6)$$

$$SSE = SST - \left(\sum_{i=1}^{Nn} SSQ_i \right) \quad (7)$$

$$F = \left(\frac{MSS}{MSE} \right) \quad (8)$$

Where; SST is the sum square of total, SSE is the sum square of error, Nn is the number factors evaluated, MSS is the mean sum of square, MSE is the sum of square of the error, df is the degree of freedom (number of levels – 1) and F is statistical F- value.

Industrial wastewaters were collected from selected industrial sources according to APHA (1998) within the country (Nigeria). The industrial wastewaters collected were subjected to electrochemical treatment and chemical treatments individually and in combinations under specified treatment conditions.

Effects of the selected treatment (electrochemical, combination of electrochemical and chemical, modified electrochemical) in removing selected contaminants (chloride ion, BOD₅, Pb, Cd, suspended solid and total solids) from typical pharmaceutical wastewaters were monitored. In the analysis of selected pollutants concentrations, procedures in (APHA (1998) were followed.

RESULTS AND DISCUSSION

Results from this study are presented and discussed in three categories (literature review, treatment of simulated pharmaceutical wastewaters and treatment of typical pharmaceutical wastewaters) as follows:

Literature Review

10

Emerging pollutants (EPs) are defined as synthetic or naturally occurring chemicals that are not commonly monitored in the environment but which have the potential to enter the environment and cause known or suspected adverse ecological and (or) human health effects. EPs are categorized into more than 20 classes related to their origin (Figure 2). The prominent classes are: pharmaceuticals, pesticides, disinfection by-products, wood preservation and industrial chemicals. There are more than 1036 emerging pollutants, their metabolites and transformation products, are listed as present in the European aquatic environment (Geissen *et al.*, 2015 ; NORMAN, 2019). In light of the potential impact of these substances on aquatic life and human health, the lack of knowledge regarding their behaviour in the environment and the deficiency in analytical and sampling techniques, action is urgently required at multiple levels. With reference to the definition, EPs are wastewaters from pharmaceutical industries. Figure 3 provides various concepts for management of emerging pollutants in the aquatic environment. Physicochemical mechanisms can also contribute to EP removal from wastewaters and surface waters. Melanie *et al.* (2019) reported that the degradation of Ciprofloxacin, enoxacin, levofloxacin, lomefloxacin and norfloxacin by oxidation processes such as aeration can be described by first order kinetics. Figure 4 provides multi-scale assessment of the ecological and human health risks derived from the acute and chronic exposure to EPs contained in surface water. Figure 5 presents photoinduced degradation of Ciprofloxacin, enoxacin, levofloxacin, lomefloxacin and norfloxacin. Best *et al.* (1960) show that efficacy of disinfectant should be scrutinised regularly to assure proper activity against major medically significant organisms. It was documented that most of the formulations studied and findings emphasized the need for caution in selecting an appropriate disinfectant for use on contaminated surface water bodies, particularly in the presence of organic material.

Martin *et al.* (1966) reported that iodine appeared to be more effective than chlorine against both the standard faecal indicators. It was documented that against *staphylococci* derived from the mouth, nose, and skin iodine appeared to be more effective than chlorine. Some microorganisms inherently developed resistance to disinfectant and even grow in disinfectant solutions. Frank *et al.* (1969) documented that resistant cells of *Pseudomonas aeruginosa* and waterborne *Pseudomonas sp.* were able to multiply in nitrogen-free minimal salts solution containing various concentrations of commercially prepared; ammonium acetate buffered benzalkonium chloride (CBC), which is a potent antimicrobial agent.

It was reported that severe problem of release of antibiotic or disinfectant resistant bacteria to the environment is potential of transferring of the resistant gene to community bacteria. In Philadelphia, examination on the transfer of plasmids pBR322 and pBR325 in wastewater from laboratory strains of *Escherichia coli* to bacteria indigenous to the waste disposal system revealed that bacterial strains isolated from raw wastewater or a plasmid free *E. coli* laboratory strain served as recipients. The transfer of the pBR plasmid into the recipient strain occurred within 25 hours co-incubation in either L broth or sterilized wastewater (Michael *et al.*, 1985). It was reported that after the co-incubation recipients exhibited both plasmid-encoded phenotypic characteristics and an altered plasmid profile, which are shown by agarose gel electrophoresis of purified plasmid DNA (Michael *et al.*, 1985). In France, comparison between *in vitro* activity of Cefoxitin with Metronidazole and Clindamycin against 322 strains of anaerobic bacteria collected from several hospitals. The antibiotic-resistant were tested using an agar dilution method. The result showed that Metronidazole and Cefoxitin inhibited at least 89% of antibiotic-resistant strains tested. Clindamycin was found to be less active in inhibited antibiotic-resistant (Dubreuil *et al.*, 1984).

Roberto *et al.* (2005) reported that amoxicillin is a widely used antibiotic, which has been found in effluents from Sewage Treatment Plant. Evaluation of ozonation treatment of pharmaceuticals was

proposed as a process for its abatement from these pharmaceuticals effluents. The results of ozonation treatments of amoxicillin containing wastewaters indicated that ozone attack was mainly directed towards the phenolic ring of the studied molecule leading to the formation of hydroxyl-derivative intermediates. In addition the study revealed that there was no strong evidence of attack of ozone on sulphur atom with sulphur-oxide formation. Pauwels and Verstraete (2006) reviewed different techniques in use for hospital generated wastewater treatment and evaluated actions of technologists and ecotoxicologists as well as public health specialists.

In Aboulhassan *et al.* (2006) reported that coagulation and flocculation with FeCl_3 proved to be effective in a pH range between 7.00 and 9.00. The process reduced surfactants and COD by 99.00% and 88.00% respectively, and increased BOD_5 to COD ratio from 0.17 to 0.41. It was concluded that precipitation coagulation process, adsorptive micellar flocculation mechanism contributed to the removal of surfactants and organic matters from the wastewaters.

Zhimin *et al.* (2006) revealed that aeration significantly improves lagoon functionality, by increasing both organic and ammonia removal. Ammonia present in the wastewaters played a critical role in antibiotics disintegration and bacterial reduction due to conversion of free chlorine to monochloramine and dichloroamine. Commonly, a chlorine dose close to breakpoint chlorination is required to achieve effective removal of antibiotics. This action usually leads to higher consumption of free chlorine than necessary in most of the wastewaters treatment.

Most of the antibiotics taken by the patients are partially metabolized and excreted through faeces and urine. Residual quantities of these antibiotics in faeces and urine reached the wastewater. The residual quantity of antibiotics exposes the bacteria in hospital wastewaters to a wide range of biocides that could act as a selective pressure for the development of resistance (Nuñez and Moretton, 2007). Increasing attention has been directed recently to the resistance of bacteria to antibiotics and disinfectants. The resistant bacteria isolated were diverse in nature. In Buenos Aires City hospital, Brazil, the bacterial population resistant to disinfectants were *Enterobacteriaceae*, *Staphylococcus spp.*, and *Bacillus spp.*, which are highly associated to nosocomial infections (Nuñez and Moretton, 2007). Study carried out in Nepal found out that healthcare liquid wastes were loaded with multiple drug resistance bacteria and seemed to pose a huge public health threat in the transfer of such resistance to the bacterial pathogens causing community acquired infections, thereby limiting our antibiotic pool (Sharma *et al.*, 2010). It has been reported that in Sweden high prevalence of Vancomycin Resistant Enterococci (VRE) was demonstrated in Swedish sewage, which can be attributed to antimicrobial drugs or chemicals released into the sewage system that sustained VRE in the system (Aina *et al.*, 2002).

In Gaza, Al Shifa hospital wastewater was compared with non-health institutional wastewater in term of the spread of antibiotic resistance with non-health institution. The study revealed that most frequently identified bacterium was *Pseudomonas sp.* (33.1%) followed by *E. coli* (30.5%), *Enterococcus sp.* (21.4%), *Klebsiella sp.* (10.4%) and *Proteus sp.* (4.5%) in the hospital wastewaters. It was established that there was high incidence of antibiotic resistance among both gram-negative and gram-positive resistant bacteria isolated. It has been documented that in Brazil extended-spectrum beta-lactamase-producing *Klebsiella pneumoniae* were detected in effluents and sludge of a hospital sewage treatment plant. This result indicated the hospital wastewater treatment plant did not demonstrate a satisfactory significant efficacy in removing pathogenic micro-organisms by allowing for the dissemination of multi-resistant bacteria into the environment. Further documentation revealed that in U.S (wastewater research division, municipal environmental research laboratory, U.S. Environmental Protection Agency) revealed effect of ultra-violet (UV) light disinfection on antibiotic resistant coliforms in wastewater effluents. The document showed that UV irradiation effectively disinfected the wastewater effluent (the percentage of the total surviv-

ing coliform population resistant to Tetracycline or Chloramphenicol was significantly higher than the percentage of the total coliform population resistant to those antibiotics before UV irradiation and the finding was attributed to the mechanism of R-factor mediated resistance to tetracycline, Mark, 1982).

In Belgium, comparisons between the antimicrobial tolerance of Oxytetracycline-resistant heterotrophic bacteria isolated from hospital sewage and freshwater fish farm water were made. The study showed that Oxytetracycline-resistant hospital heterotrophs displayed a higher frequency (84%) of Ampicillin (Amp) tolerance compared to the Oxytetracycline-resistant heterotrophs from the freshwater fish-farm site (22%). In Austria, evaluations of antibiotic resistance of *E. coli* in sewage and sludge were conducted. The study revealed that the highest resistance rates were established in *E. coli* strains of a sewage treatment plant which treated both municipal sewage and sewage from a Hospital. In Nigeria, similar investigations demonstrated that hospital wastewaters played significant roles in the influence on the qualities of the bacteriological and physiochemical parameters on the receiving surface water bodies (environment), which can be attributed to increased amount of organic matter and essential nutrients in hospital wastewater. It was reported that most of the hospital effluents with other sewages released to water bodies (lakes, rivers, ponds or streams) or ground water bodies (hand dug and shallow wells), which are served as media for transfer of resistant bacteria and their genes in aquatic systems. As these water bodies are the major sources of drinking water (directly or indirectly) for human and animal consumption, its pollution may contribute to the maintenance bacterial antibiotic resistance in the environment and even the spread of bacterial antibiotic resistance (Mesdaghinia *et al.*, 2009).

In France, a study was conducted to trace whether antibiotic-resistant *Pseudomonas aeruginosa* isolated from hospitalized patients recovered in the hospital effluents. The study of genotyped both clinical and wastewater isolated antibiotic-resistant was determined by using pulsed-field gel electrophoresis (PFGE). The study revealed that there was no common PFGE pattern in antibiotic-resistant *P. aeruginosa* from humans and wastewater. It was concluded that antibiotic resistance profile of wastewater isolated antibiotic-resistant was different from that of clinical isolates (Tumeo *et al.*, 2008).

Jara *et al.* (2007) presented electro-oxidation treatment of aqueous solutions containing the antibiotics Ofloxacin and Lincomycin with different anodes (Ti/Pt, DSA1 type, graphite and three-dimensional (3D) electrode made of a fixed bed of activated carbon pellets). It was reported that effectiveness of the treatment of wastewater containing pharmaceuticals was assessed based on antibiotics and bacteria removal, as well as the electro-oxidation mechanism. The electro-oxidation was found to follow first order kinetics at the anode surface when Na_2SO_4 was at a low concentration (0.02 Normality). At lower concentration of Na_2SO_4 Ofloxacin was efficiently oxidized at the rate of $50 \text{ mgcm}^{-2}\text{A}^{-1} \text{ h}^{-1}$ for the bi-dimensional Ti/Pt electrode. It was observed that Lincomycin was oxidized with slow overall kinetics, which can be attributed to difficult deprotonation. It was concluded that the three-dimensional electrode would be the most appropriate for continuous industrial-scale process of aqueous solutions containing the antibiotics Ofloxacin and Lincomycin treatment.

In Watkinson *et al.* (2007), antibiotic resistance (AR) patterns of 462 *Escherichia coli* isolates from various wastewater, different surface water sources, and oysters were evaluated. The study revealed that the rates of AR and multiple-AR among isolates from surface water sources adjacent to wastewater treatment plant discharge sources were significantly higher ($p < 0.05$) than other *Escherichia coli* isolated from other sources. The rates of AR among *Escherichia coli* isolated from oysters exposed to wastewater treatment plant discharges were lower (less than 10%) than other *Escherichia coli* isolated from other sources.

Pedro *et al.* (2009) concluded that detrimental effects of anti-infective on aquatic microbiota are possible with the constant exposure of sensitive species. Indirect impact on human health cannot be ruled

out when considering the potential contribution of high anti-infective concentrations to the spreading of anti-infective resistance in bacteria.

Jury *et al.* (2010) concluded that precise explanations would be required to confirm these phenomena and experimental approaches, including culture-independent methods are suggested.

Emad and Malay (2010) concluded that the photo-Fenton process can be used as pre-treatment for antibiotic degradation and biodegradability enhancement of antibiotic wastewater containing amoxicillin and cloxacillin.

In Chelliapan *et al.* (2006; 2011) reported that anaerobic technology is a promising alternative for pharmaceutical wastewater treatment. In Chelliapan and Golar (2011), an Up-Flow Anaerobic Packed Bed reactor was employed to treat pharmaceutical wastewater containing antibiotics. Effect of organic loading rate (OLR) was assessed by modifying feed substrate concentration and hydraulic retention time (HRT). Performance of the system was based on COD removal, volatile fatty acid (VFA), gas production, methane yield and pH. The study showed that COD reduction was between 60 and 70% at an OLR between 1.5 and 4.6 kg COD.m⁻³.d⁻¹, which indicates that the biomass had acclimated to the antibiotics. An increase in the OLR soluble COD removal efficiency decreased to 50% at an OLR of 5.6 kg COD.m⁻³.d⁻¹, which indicates that OLR have effect on the methanogens.

Honarbakhsh (2011) examined the impact of antibiotic resistant bacteria from final sewages on water receiving bodies. On wastewater collected Phylogenetic analysis of the 16S rRNA gene sequences was performed to develop the composition and structure of the four microbial communities. The distribution of β -lactamase genes across the four sites was also assessed. Clone library information and TRFLP profiles revealed that the four communities were all controlled by Betaproteobacteria, which constituted approximately two thirds of the final effluent community. The diversity and abundance of other bacterial phylotypes varied across sites. Bacterial diversity included 9 phylotypes in the final effluent, 15 and 13 phylotypes respectively in the downstream. Bacteria were isolated from the same samples using culture-dependent techniques, which allowed to link antibiotic resistance to particular bacterial species. Clone libraries were dominated by Betaproteobacteria, culturable isolates mainly belonged to the class of Gammaproteobacteria. Analysis of the isolates from the final effluent exhibited the presence of *Bacillus*, *Enterobacter*, *Acinetobacter*, and *Staphylococcus* strains, while samples collected downstream from the plant were categorized by species belonging to the genera *Brevibacterium*, *Chryseobacterium*, *Aeromonas* and *Delftia*. All the isolates were resistant to amoxicillin, and most displayed resistance to multiple antibiotics. Phylogenetic analysis revealed that the distribution of the *bla* TEM4 gene is divided to two main clusters. The first cluster contains sequences that are exclusively detected at the plant and receiving water, but not at the upstream site, while sequences of the second cluster were present at all of the four sites.

Shreeshivadasan and Paul (2011) concluded that changes in the organic loading of pharmaceutical wastewater affected the treatment performance of the anaerobic reactor, and at high OLRs, anaerobic reactor was not able to withstand the short HRT, probably due to the intricacy of pharmaceutical wastewater.

Thompson *et al.* (2013) investigated the presence of methicillin-resistant *Staphylococcus aureus* (MRSA) in untreated hospital wastewaters (UHW), their transmission into the receiving sewage treatment plant (STP) and survival through the STP treatment. The study isolated 224 *Staphylococcus aureus* strains from UHW-1, UHW-2 and its receiving STP inlet (SI) and post-treatment outlet (SO). These strains were categorized using the PhP and RAPD-PCR methods. The strains were tested for their antibiotic resistance patterns. Resistance of the microbials to cefoxitin and the presence of *mecA* gene were used to identify MRSA isolates. In the study, 11 common (C) isolates and 156 single (S) PhP-RAPD isolates were identified, with two multidrug resistant (MDR) C- isolates found in H₂, SI and SO. These C- iso-

lates strains showed resistance to cefoxitin and vancomycin. The mean number of antibiotics to which the strains from UHWW were resistant (5.14 ± 2) was significantly higher than the STP isolates (2.9 ± 1.9 , $p < 0.0001$). Out of the total samples, 131 (68%) isolates were MRSA strains, 24 isolates were vancomycin resistant. MDR strains (including MRSA) were identified to be more prevalent in hospital wastewaters than in the STP. The study provided evidence of the survival of MRSA strains in UHWWs and their transit to the STP. It was reported that MRSA strains survived in the final treated effluent and chlorination stage. It was concluded that there is the needs to further investigate the load of MRSA in hospitals' wastewaters and possible their survival in STPs.

Katouli *et al.* (2012) evaluated the presence and survival of antibiotic resistant bacteria in untreated hospital wastewaters (UHWW) and transmission of antibiotic resistant bacteria in untreated hospital wastewaters to the receiving sewage treatment plant (STP) in South East Queensland (SEQ), Australia. The study revealed that in the *E. coli* strains collected from UHWW, seven common (C) PhP-RAPD species were found frequently and in most of weekly samples with multi-drug resistant (MDR) C-species found in STP-I. It was revealed that on three occasions multi-drug resistant (MDR) C-species found in STP-O. In *S. aureus* strains, seven C- species were frequently found in a majority of samples with two MDR C-species in STP-I. It was showed that on two occasions two MDR C-species in STP-O. The study concluded that some MDR bacterial strains found in UHWW may have the ability to survive, transmit to the STP and to the final treated effluent before being released into surface water bodies. Abargues *et al.* (2013) evaluated the effect of light, oxygen and microalgae on removal of the endocrine disrupting compounds 4-(1,1,3,3-tetramethylbutyl)phenol, technical-nonylphenol, 4-n-nonylphenol, and BPA from the effluent of an anaerobic MBR. Results demonstrated that the removal rates of these compounds differed with each post-treatment method and that aeration (oxygen) resulted in the highest removal ratios indicating the importance of an aerobic step in EDC degradation; a mass balance also showed that chemical oxidation was more important than sorption processes.

Choe *et al.* (2013) compared perchlorate-selective ion exchange, biological reduction and catalytic treatment for perchlorate removal based on the environmental impacts of consumable inputs normalized to the mass treated, in a lifecycle analysis. Because resource consumption during the operational phase comprises greater than 80% of the total impacts of these technologies, the analysis indicates that ion exchange is competitive, but emerging technologies also show great promise from an environmental sustainability perspective.

Kovalova *et al.* (2013) compared the removal efficiencies of micro-pollutants in hospital wastewater using O_3 , O_3/H_2O_2 , PAC, and UV light with or without TiO_2 . They found that the majority of wastewater micropollutants can be removed by ozone and PAC, while some recalcitrant compounds, like diatrizoate, can only be removed by high UV doses. Combined treatments of O_3/H_2O_2 and UV/ TiO_2 did not improve removal efficiency over single treatments of ozone and UV. The efficiency of MBRs and ozonation in removing endocrine disruptive potentials was studied for use in treatment of hospital wastewater (Maletz *et al.*, 2013). Treatment by MBRs reduced estrogenicity of sewage while ozonation efficiently removed most measured compounds. Yet another subset of studies in this category evaluated whole plants and either compared different treatment trains or compared processes within a single plant to each other in terms of effectiveness for emerging pollutant abatement. The concentrations and removal rates of ARGs were measured in three municipal WWTPs employing conventional treatment followed by different advanced treatment systems [biological aerated filter, constructed wetland, and UV disinfection] (Chen and Zhang 2013). The authors reported ARG reductions of 1 – 3 orders of magnitude through three conventional activated sludge processes. However, advanced post-treatment systems differed with orders

1–3 of reductions in ARGs in constructed wetlands, 0.6–1.2 orders in the biological aerated filter, and no apparent decrease by UV disinfection.

Flores *et al.* (2013) evaluated a full-scale drinking water treatment plant and several pilot treatment systems with a number of conventional (prechlorination, coagulation, sand filtration and ozonation) and advanced (RO, reverse electrodialysis and GAC adsorption) water treatment processes for their ability to remove perfluorinated compounds. Authors found the most efficient process was RO, which resulted in 99% removal of the studied pollutants. Other processes that showed removal of both the pollutants were adsorption onto GAC and reverse electrodialysis. All of the conventional processes proved to be fully ineffective. Concentrations of antibacterial chemicals triclocarban and triclosan and a triclosan biodegradation product methyltriclosan (MeTCS) were monitored in the liquid phase throughout a wastewater plant by Lozano *et al.* (2013). Triclocarban and triclosan were primarily removed by sorption and settling, though concentrations of both also decreased during nitrification denitrification and triclosan concentration decreased during the activated-sludge stage. Ozonation followed by sand filtration and PAC followed by either sand filtration or UF were tested in parallel for removal of 70 potentially problematic substances and reduction of ecotoxicological effects at large scale WWTPs over a year (Margot *et al.*, 2013).

Adina *et al.* (2013) reported that the degradation of 4-chlorophenol by an electrochemical advanced oxidation process. It was stated that several authors have proposed the following possible pathways of oxidation of some emerging pollutants by electrochemical processes. The pathways are as follows:

- i. 4-chlorophenol dechlorination to phenol;
- ii. hydroxylation of phenol to hydroquinone;
- iii. dehydrogenation of hydroquinone to benzoquinone;
- iv. oxidation of benzoquinone (with aromatic ring cleavage) to aliphatic carboxylic acids such as maleic acid, fumaric acid, malonic acid;
- v. oxidation of maleic and fumaric acids to oxalic acid,
- vi. formic acid to carbon dioxide and water

Rahim *et al.* (2014) revealed that the mean concentrations of GM, CHL and ceftazidime resistant bacteria in raw wastewater samples were 1.24×10^7 , 3.29×10^7 and 5.54×10^7 colony forming unit per 100 ml, respectively. There was a variation in prevalence of diverse groups of ARB in MWs and HWs. All WWTPs, there were decreased in the concentrations of ARB. It was established that high concentrations of ARB were found in the final effluent of WWTPs. In line with ARB, different groups of ARGs were found frequently in both MWs and HWs.

Sourav and Alok (2014) reviewed few treatment processes that are effective in remediating the pollution load in the pharmaceutical wastewater in an environmental sustainable manner (Table 2).

In Yamina *et al.* (2014), twelve cadmium-resistant bacteria were identified and isolated from hospital wastewaters. The cadmium-resistant isolated were characterized into both Gram-negative [75%] and Gram-positive [25%]. All isolated bacteria showed co-resistance to zinc and mercury in aqueous solutions. Isolated bacteria were antibiotic resistant and tolerated NaCl to a significant concentration of NaCl. The cadmium-resistant species (*Klebsiella pneumoniae* and *Pseudomonas aeruginosa*) were the most resistant to cadmium. The species *Klebsiella pneumonia* resisted to the highest concentrations of zinc and mercury. The results of toxicity tests on *Vibrio fischeri* revealed that the DI_{50} [15 minutes] as low as 0.07 carried away 50% luminescence inhibition.

Amenu (2014) revealed that there was no correlation between antibiotic-susceptibility and susceptibility to disinfectants in hospital strains and that there was cross-resistance between triclosan and antibiotics in *Pseudomonas aeruginosa*, which in turn showed that exposure of a clinically significant bacterium to the antiseptic triclosan efficiently can select for multi-drug resistant (MDR) derivatives, which include high-level resistance to an ant *pseudomonas* drug.

Rongjun *et al.* (2015) conclude that RBCs are effective in the treatment of wastewater, but RBCs are rarely use for treating antibiotic pharmaceutical wastewater.

Benson *et al.* (2015) revealed that there was a very high phenotypic multiple resistance within the isolates, which were confirmed by genetic analyses.

Birošová, *et al.* (2015) concluded that stabilized sludges represent sources of methicillin, penicillin, ampicillin and ciprofloxacin resistant *S. aureus*.

Huan *et al.*, (2018) shows that the emission of dissolved organic matter in wastewater after electrochemical treatment could accelerate estrogen degradation and play a positive role on the pollutant transformation in the environment.

Electrochemical Treatment of Simulated Pharmaceutical Wastewater

Tables 3 and 4 present summary and results of statistical analysis (fractional factorial experiment and analysis of variance) of the effect of the selected factors on the performance of electrochemical treatment of pharmaceutical wastewaters. Table 3 revealed that performance of the treatment can be classified into two categories as performance greater than 54.88% and performance less than 54.88%. Experiments 2, 11, 12, 15 and 16 provided performance higher 54.88% which indicated that factors at higher levels in the above stated experiments had positive effects on the performance of electrochemical treatment of pharmaceutical wastewaters. From the tables, 54.88% was the mean performance of the process (expected performance when all the selected factors are at their low levels). Experiments 3,4,5,6, 7, 8, 9, 10, 13 and 14 were performance less than 54.88%. This result shows that factors at high level in experiments 3,4,5,6, 7, 9, 10, 13 and 14 contributed negatively (reduced) to the performance of electrochemical treatment of pharmaceutical wastewaters.

For effective performance of electrochemical system the results indicated that experiments 3,4,5,6, 7, 8, 9, 10, 13 and 14 needs to be minimized, while experiments 2, 11, 12, 15 and 16 must be optimized to save operational cost. Tables 4(a and b) present the detailed statistical analysis. Table 4a presents summary of analysis of variance and Table 3b shows basic computation of the analysis. From these Tables factors with significant effect were current applied ($F_{1,7} = 9.80$), concentration of $\text{Ca}(\text{OCl})_2$ ($F_{1,7} = 11.34$) and volume of the wastewater used ($F_{1,7} = 33.79$) at 95% confidence level ($F_{1,7} = 5.59$ critical value). Separation distance between the electrodes ($F_{1,7} = 4.27$) was another factor that had significant effect at 90% confidence level. Although, other factors (Concentration of BOD_5 , Depth of the Electrodes in the Wastewater, Temperature of the Wastewater and Treatment Time) had effect on the performance of the treatment process, but the effects were not significant at 90% confidence level. These can be attributed to the presence of $\text{Ca}(\text{OCl})_2$, which acted as oxidizing agent and electrolyte to speed up the treatment process.

Electrochemical and Chemical Treatment of Typical Pharmaceutical Wastewater

Table 5 shows the results of performance evaluation of each the selected wastewater treatment methods in respect to wastewaters from pharmaceutical industry. From the table efficacies of electrochemical

method in removing chromium, BOD₅, SS, colour, chloride, total solids, lead, cadmium and zinc were 100, 88.8, 96.6, 80.0, 12.5, 92.9, 100, 100 and 76.7% using 0.43 MJ (30Wh per litre). For chemical treatment method 82.5, 86.0, 70.2, 60, -100, 48.2, 100, 100, and 65.6% efficacies were achieved using 1200 mg/L of Ca(OCl)₂. For modified electrochemical treatment method 100, 99.1, 98.6, 90.0, -205, 58.2, 100, 100 and 80.5% efficacies were achieved using 1.61MJ(112Wh per litre) and for combination treatment of electrochemical and chemical treatment method efficacies of 100, 99.1, 99.4, 80.0, -20, 92.9, 100, 100 and 85.4% were attained using 0.43 MJ (30 Wh per litre) and 450 mg/L of Ca(OCl)₂. Efficacies variation by electrochemical treatment may be attributed to quantity of current through the wastewater. Comparing quality of treated wastewaters with environmental standard limits in Nigeria, it can be stated that with exception of BOD and suspended solids concentration other pollutants met FEPA limits, indicating the method can be used effective for pharmaceutical wastewaters but must be followed by sedimentation process to remove suspended solids and left over BOD.

Cost analyses: Comparison of the performance and efficiency of the three technologies studied can be summarized as follows: under similar conditions of aluminium concentration and pH the three technologies attain similar results. For this reason, comparison of the operating costs of the three processes is a critical issue in recommending the use of one of the technologies. In this context, it is important to note that the aim of this study has been to compare the operating costs of the three dosing technologies, and to estimate the total costs of each one. Thus, a preliminary economical evaluation has been conducted, in which the items that can be considered to be the same in both processes, such as labour cost and management of the sludge have not been included in the calculations. In this context, the following assumptions have been made for the economical estimation (Pablo et al., 2008):

- The labour costs required in the three processes should be similar, despite the management of reagents involved in the conventional dosing of reagents, because the three processes can easily be automated. Also, the amount of sludge produced in the three processes must be similar, and therefore, the costs related to management of the sludge can be considered to be the same. The technique of cost estimate in literature such as Oladepo *et al.* (2011) was adopted for capital and operational costs.
- The electrocoagulation cell is properly designed, that is, the turbulence generated by the gas bubbles emerging from the electrode surfaces is conveniently used to promote mixing of the electrodisolved coagulants, and the electroflocculation process. In principle, this fact should not increase the cost of the cell, as a simple layout of the electrodes in a parallel and slightly slanting position allows promotion of both effects. As a consequence, additional mechanical mixing is not required to promote either coagulation or flocculation processes. In addition, in the electrochemical process it is not necessary to consider the energy consumption derived from the dissolution of solid coagulants (salts) to prepare the liquid reagent to dose the coagulation process.
 - To estimate the power necessary for mixing in conventional coagulation and modified conventional coagulation processes, the velocity gradient G (s⁻¹) has been used. This parameter is a function of the mixing velocity, the type of impeller, and the ratio between the tank and the impeller sizes as follows:

$$G = \sqrt{\frac{P}{\mu \times V}} \quad (9)$$

Typical values of parameter G are reported in the literature for the coagulation stage: 900 s^{-1} for 30 s, and for the flocculation stage: 25 s^{-1} for 30 minutes. To calculate the mixing power necessary to prepare the coagulant solution, the author used a medium value for G of 700 s^{-1} for 10 minutes (Viessman and Hammer, 1993; Pablo *et al.*, 2008).

- The operating costs of the conventional and modified conventional coagulation process involve the costs related to the price of the coagulant reagents, and the energy consumption required for mixing in coagulation and flocculation processes. In addition, solid coagulants are used, it is necessary to consider the mixing required to prepare the coagulant solution. The energy consumption related to the pumping of the coagulant solutions was not considered to be negligible. To estimate the energy costs, one must take into account that the prices of electricity are highly dependent on the particular country. The present unitary electricity cost for industrial use in Nigeria is around $0.23 \$\text{kWh}^{-1}$ (currently $1 \text{ US\$} = 365 \text{ Nigeria Naira}$).
 - The operating costs of the electrocoagulation process involve the price of the aluminium rod (used as electrodes) and the energy costs for their electrodisolution. The results obtained in the study of electrodisolution of aluminium have been borne in mind in estimating the energy consumption for the electrodisolution of aluminium. Previous study has shown that the concentrations of aluminium electro-dissolved are more than those values predicted by Faraday's Law, due to chemical corrosion of the electrodes. Thus, the aluminium concentrations have been related to the Faraday's Law by an empirical equation as follows (Pablo *et al.*, 2008):

$$C_{Al} = 100 \left(\left(\frac{I \times W_{Al}}{F \times n \times q} \right) X \right) \quad (10)$$

In electrochemical process the power consumption P (W) is given as follows:

$$C_E = \left(\frac{I \times E_v}{C_{Al} \times q} \right) = 100 \left(\frac{F \times n \times E_v}{W_{Al} \times X} \right) \quad (11)$$

The voltage (E_v) in the electrodisolution of aluminium has been set for this estimation according to the experimental results obtained in previous work, although this parameter is strongly dependent on the conductivity of the raw water treated.

- Regarding the separation of solids (pollutants with reduced solubility), in the case of conventional coagulation, the most favourable conditions have been assumed: the solids can settle rapidly, and therefore, it is not necessary to use the dissolved air flotation processes that would increase the cost of the treatment. In this context, in the electrochemical process the gas bubbles produced on the surface of the electrodes promote the separation of solids to the top of the cell (electroflotation process). Taking all of this into account, the separation of solids has not been considered to increase the cost of either of the coagulation processes.

Concerning the operational comparison of the three processes, it was found that the changes in pH are different in the three dosing technologies. For this reason, it was necessary to adjust the final pH of the raw wastewater to obtain recommended pH value. Figure 6a presents relationship between cost of treatment and efficacy of selected wastewater treatment techniques in removing

selected pollutants from pharmaceutical wastewater. Figure 6b shows relationship between rate of change in cost of treatment per unit percentage and selected treatment techniques used. From the figures it can be seen that electrochemical and modified electrochemical (assisted electrochemical) treatment techniques are among the cost effective techniques in treating pharmaceutical wastewater.

FUTURE RESEARCH DIRECTIONS

As a consequence of these uncertainties and increase in diseases, the designs as well as management strategies of water and wastewater treatment plants have to include effects of EPs on biological treatment processes, expected end products after chemical oxidation of EPs and management of wastes from treatment plant.

CONCLUSION

It can be concluded based on the study that:

- a) wastewaters from pharmaceutical activities contain emerging pollutants,
- b) there are more than 1036 emerging pollutants and various concept for management of emerging pollutants in the aquatic environment,
- c) there are twenty-one antibiotic-multi-resistant strains,
- d) in Belgium, Oxytetracycline-resistant hospital heterotrophs displayed a higher frequency (84%) of Ampicillin (Amp) tolerance compared to the Oxytetracycline-resistant heterotrophs from the freshwater fish-farm site,
- e) in Austria, the highest resistance rates were established in *E. coli* strains of a sewage treatment plant,
- f) in Nigeria, most of the hospital effluents with other sewages released to water bodies are served as media for transfer of resistant bacteria and their genes in aquatic systems,
- g) in France, antibiotic resistance profile of wastewater isolated antibiotic-resistant was different from that of clinical isolates and there are cadmium-resistant species (*Klebsiella pneumoniae* and *Pseudomonas aeruginosa*),
- h) in Gaza, most frequently identified bacterium was *Pseudomonas sp.* (33.1%) followed by *E. coli* (30.5%), *Enterococcus sp.* (21.4%), *Klebsiella sp.* (10.4%) and *Proteus sp.* (4.5%) in the hospital wastewaters,
- i) In France, there was no common pulsed-field gel electrophoresis pattern in antibiotic-resistant *P. aeruginosa* from humans and wastewater,
- j) In hospital wastewater the dominated antibiotic resistant bacteria were ciprofloxacin, penicillin, methicillin, ampicillin and vancomycin resistants,
- k) the bacterial population resistant to disinfectants were *Enterobacteriaceae*, *Staphylococcus spp*, and *Bacillus spp*, which are highly associated to nosocomial infections,
- l) current applied through the electrodes, concentration of $\text{Ca}(\text{OCl})_2$, volume of the wastewater and separation distance between the electrodes were significant factors that influence electrochemical treatment of pharmaceutical wastewaters at 90% confidence level,
- m) Electrochemical treatment of pharmaceutical wastewaters using public electricity source is economical when compared with other treatment processes evaluated.
